Table of Contents

1. Introduction
2. Errata/Change Log
3. LINKS TO RELEVANT INFORMATION IN THE ONLINE NSSDC
INFORMATION SYSTEM
4. Catalog Materials
 - a. Associated Documents
 - b. Core Catalog Materials

1. INTRODUCTION:

The documentation for this data set was originally on paper, kept in NSSDC's Data Set Catalogs (DSCs). The paper documentation in the Data Set Catalogs have been made into digital images, and then collected into a single PDF file for each Data Set Catalog. The inventory information in these DSCs is current as of July 1, 2004. This inventory information is now no longer maintained in the DSCs, but is now managed in the inventory part of the NSSDC information system. The information existing in the DSCs is now not needed for locating the data files, but we did not remove that inventory information.

The offline tape datasets have now been migrated from the original magnetic tape to Archival Information Packages (AIP's).

A prior restoration may have been done on data sets, if a requestor of this data set has questions; they should send an inquiry to the request office to see if additional information exists.

2. ERRATA/CHANGE LOG:

NOTE: Changes are made in a text box, and will show up that way when displayed on screen with a PDF reader.

When printing, special settings may be required to make the text box appear on the printed output.

SKYLAB EUV DATA ON MAGTAPE

73-027A-06A

SOUV-00040

This data set has been restored. There were originally 1,103 Binary, 7-Track, 556 BPI tapes, 48 of these tapes were bad. There are 64 restored tapes. The DR tapes are 3480 cartridges and the DS tapes are 9-track, 6250 BPI multi-filed. The tapes were created on a 6600 computer. The DR and DS numbers along with the corresponding D numbers and the time spans are as follows:

DR#	DS#	D#	FILES	TIME SPAN

SKYLAB SOLAR EUV DATA

73-027A-06A

This data set consists of numerous tapes that are listed below and printed on several following sheets of printout. The tapes are 7 track, 556 BPI, binary, multi-filed. The tapes were created on the CDC 6400 computer.

0. INTRODUCTION

This is one of a series of documents describing the data, their use and formats, obtained by the Harvard EUV Spectrometer, the S055 Instrument included in the Apollo Telescope Mount part of Skylab. In particular, this tomus parvus is to introduce the data tapes which contain the raw scientific data. In order to present a workable knowledge of the data, the first section is a description of the methods used to gather the data and process them into final form. The second section describes the tapes themselves. A list of problems (probably incomplete) and diagnostic methods form the third section completing this report. A more general and complete overview of the mission and of the types of data available is in the Data Handbook by William Harby and Edmond Reeves.

A "Caveat" must be observed with respect to the values given on these pages - they should not be used when a fair amount of accuracy is needed. Rough values are included here to allow simple calculations to be made easily.

For efforts in assembling the data I would like to thank many people at Harvard College Observatory, NASA, and Ball Brothers Research Corporation, particularly William Demos. This work was done under NASA contract NAS5-3949.

1. DATA GATHERING AND PROCESSING

The S055 spectroheliometer digitally measured light intensities in the extreme ultraviolet. These data and others giving the configuration of the instrument and of the ATM systems were relayed to the ground and stored in several different forms on magnetic tape. Finally the data were organized and formatted onto the Scientific Users' Tapes.

1.1 EXTREME ULTRAVIOLET SPECTROHELIOMETER

The instrument (Fig. 1.1-A, Table 1.1-I) can be regarded as three serial subsystems. The first is a telescope with an off-axis paraboloidal mirror. The mirror is gimbal mounted, and servos control either raster scans of 5.5×5 (arc min)² or line scans of 5.5 arc min $\times$ 5.0 arc sec. The rasters take 5.55 minutes to complete and so have coarser temporal resolution than the 5.50 second line scans. When not scanning the servos allow the mirror to be pointed within an area of the raster, however the mirror was usually left in the stow position. The pointing and orientation of the instrument as a whole are determined by those of the ATM baseplate on which it is mounted.

The solar image is focussed onto the entrance slit of the spectrometer, the second subsystem. The slit size defines the spatial resolution of 5.0 arc sec (or about 4000 km perpendicular distance at 1 A.U.). The light is diffracted at near normal incidence from a grating in a modified Johnson-Onaka Mount. A stepping motor and cam rotate the grating allowing the spectrum to be scanned past the exit slits. Within the wavelength range of the spectrometer the selection of a set of wavelengths for a raster or line scan is achieved by stopping the grating.

There are seven exit slits each with its own detector. Detector 1 is the primary detector for spectral scans since the spectrometer design provides perfect horizontal focus for it at 1350 and $450 \text{ \AA}$; it has access to the entire spectral region for which the instrument was designed, 1350 to $296 \text{ \AA}$; and it has the smallest bandpass ($1.6 \text{ \AA}$ FWHM) of any of the detectors.

Figure 1.1-A Spectroheliometer Optical Schematic

TABLE 1.1-I
Selected Instrument Parameters

Telescope

Scan Size: 5.5 x 5 arc min
Scan Velocity: 1 arc min/sec
Scan Time: 5.55 min
Scan Lines: 60
Samples per line: 132

Spectrometer

Spectral Range: 1350-296⁰ Å
Spectral Resolution: 1.6⁰ Å (detector 1)
Scan Rate: 4.8⁰ Å/sec (0.2⁰ Å/step)
Scan Time: 3.8 min
Detector Sampling Rate: 24/sec
Dynamic Range: 0 to 16383/.041 sec*
Number of Detectors: 7

*Detector 2, having only 13 downlink bits, has a range of 0 to 16382/.041 sec.

The increase in the bandpass of detector 1 due to defocussing reaches a maximum of $0.6 \text{ \AA}$ at $950 \text{ \AA}$. Detector 1 and the other six, which have bandpasses of 4 to $8 \text{ \AA}$, are used together in non-spectral modes. Detector 2 has an attenuator which reduces the incoming intensity by a factor of 25.

The third subsystem consists of the detectors and their recording electronics. The detectors can be turned on independently of each other. The output pulses are accumulated in 16-bit counters during a 41 ms integration time. The data from the low order 14 bits in each counter, except detector 2, are shifted out 24 times per second. Neither the lowest bit in counter 2 nor the two high order bits of any counter are transmitted. The range of values telemetered is 0 to 16393 counts per 0.41 sec. with only even values being reported from detector 2.

The instrument looks through an aperture door on the ATM cannister which can open or close automatically at sunrise and sunset and can switch the detectors off when it is closed. Overly high current in the detectors can also turn the detector voltage off automatically.

The instrument was operated either by a crewman on board Skylab or by ground command from Houston. Interlocks were generally successful in preventing the operation of the mirror and grating simultaneously. The normal instrument modes can thus be listed as mirror, grating, or STOP. As such they are described below under the appropriate subsystem and a description of the actual operation of the instrument can be found in the Data Handbook and the S055A Experiment Handbook.

1.1.1 Telescope Operation (Mirror)

* The mirror motion consists of a back and forth motion parallel to the X-axis (fig. 1.2-A) and a downward step at the end of each line when rastering. Figure 1.1-B shows the appearance of a raster mirror trace suitable for reconstructing a picture from raw data. The scan velocity of 1 arc min/sec and the scan time of 5.5 seconds result in a line about 5.5 arc min long. Each line contains 132 data samples whose average spatial separation is 2.5 arc-sec; due to the 5 arc-sec

slit size and motion there is considerable overlap of adjacent samples. With each set of data samples from the detectors, the one bit S/EOR-EOL indicator (Start/End of Raster-End of Line) is included. Under normal scanning operations it is on (1) within a line, goes off (0) on the last data point on one line, and stays off for the first two data points on the returning line. The ends of lines are marked in this way for both directions of mirror travel and for raster as well as line-scan data.

The mirror vertical motion is stepwise from the top with a 5 arc-sec separation between lines in the negative Y direction (Fig. 1.2-A).

A raster contains 60 lines and takes 5.5 minutes to gather data. When rasters are running continuously each takes 5 minutes 33 seconds including the travel time to the stow position and then to the right of line one to start the next raster. The S/EOR-EOL goes off on the last point of line 60 and does not come on again until line 1. During the time the mirror is not scanning normally the S/EOR-EOL bit stays off.

The mirror position is monitored on a grid system of lines and steps. The line number, Y-POS, corresponds to the lines of the raster. The step number, X-POS, goes approximately from -2 at the left end of a line to 65 at the right end. If within a line data positions are numbered starting at the left end, the step number, S, associated with the position numbered n is:

$$S = \frac{1}{2}n - 2$$

This is accurate to 2 steps.

Besides monitoring the mirror motion, this grid system is used to select the line on which a line scan is made and the location of the stow position or of any point of interest within the field of the telescope. All positioning is done with integer values of steps and lines less than or equal to 60.

The behavior of the mirror is selected by setting the 2 bit mirror mode as given in table 1.1-II.

Figure 1.1-B Mirror Motion
Projection of observed point onto visual field

TABLE 1.1-II

MIRROR MODES

MODE		ABBREVIATION	DESCRIPTION
(2 bits)	(Octal)

DETECTOR POSITIONS AT OPTICAL REFERENCE COMPARED TO DETECTOR I SPECTRA

NOTE: Spectra are from Detector I (tape/file = 35242/81, 33531/8)

Figure 1.1 Grating Scan

1.1.2 Spectrometer Operation (Grating)

The grating is driven by a cam and a stepping motor. The cam is shaped such that the ultraviolet spectrum is passed by detector 1 from 1350 Å to 296 Å where there is a flyback. The stepping motor is synchronized with the sampling so that the motion occurs during the .6 milliseconds within each 24th of a second when the detectors are not integrating. A complete scan has 5496 ± 5 steps and takes about 3 min 49 sec; the flyback is accomplished in about 420 steps. During the scan each step shifts the spectrum about .2 Å. The spectrum as seen by detector 1 is shown in Figure 1.1-C.

The position of the grating is monitored by the grating step counter. This is a 13 bit accumulator which is incremented by 1 each time the grating is stepped. To synchronize the counter and the grating position the counter is reset to zero when a reference bit, controlled by the grating, changes from zero to one. There are two reference bits, optical reference (OR), and mechanical reference (MR), either of which can be used. The choice is determined by the reference select (REFSEL) bit, which is set on command: when reference select is on (1) the optical reference bit is used, and when it is off (0) mechanical reference is used. The normally used reference bit, optical, is on when the zero order image from the grating strikes a white light detector. This occurs for approximately 35 steps during a scan. The white light detector is positioned such that the optical reference bit comes on when all the detectors are on the Rowland circle and thus in focus. This is the principal grating position for rasters and line scans.

The other reference bit, mechanical, is turned on mechanically shortly after flyback and remains on for over 600 steps. Mechanical reference comes on 104 ± 3 steps before optical reference.

The grating behavior is selected by setting the 3 bit grating mode as given in Table 1.1-III.

Exit slit data are in Table 1.1-IV. The wavelengths seen at each detector have a nearly linear relation to the optically referenced grating step. Wavelengths can be calculated from the coefficients in Table 1.1-IV to an accuracy of ± 2 Å. Table 1.1-V is a list of useful grating positions.

TABLE 1.1-IV
EXIT SLIT PARAMETERS

Detector NO.	Bandpass Å (at focus)	Step (Optical Reference) to wavelength conversion ₀ Nominal wavelength = $A_0 + A_1 S$ (accuracy ± 2 Å)	
		A_0 (Å)	A_1
1	1.6	1336.4	- .2112
2*	8.3	1219.3	- .2113
3	4.0	1032.2	- .2108
4	4.0	977.4	- .2111
5	8.3	896.0	- .2109
6	4.0	625.6	- .2090
7	4.0	553.4	- .2093

*An attenuator mounted in front of the second exit slit reduces the flux by a factor of 25.

1.2 TIME AND POINTING

In addition to data from the spectroheliometer, the data tapes contain data derived from the time and pointing systems of ATM. The clock contained a 30-bit register which was incremented every quarter second. It could also be incremented or decremented on command.

The pointing of the cannister, its problems, and its fine points, are discussed fully in the Pointing Reference Handbook. The purpose of this introduction is to define the quantities on the data tapes and to show how they can be used if the tolerance of error is not too small.

The pointing of the ATM cannister was sensed and controlled through three quantities: γ_x (GAMX), γ_y (GAMY), γ_{RR} (GAMRR). These are illustrated in Figure 1.2-A. The first two are displacements along two perpendicular directions from the center of the solar disk as given by the fine sun sensor. The third, γ_{RR} , is the rotation of the γ_y from solar north, clockwise being positive. The pointing of the S082B instrument, $\overrightarrow{NRL}$, is offset from the fine sun sensor direction, $\vec{\gamma}$, by the S082B bias:

$$\overrightarrow{NRLB} = \vec{\gamma} - \overrightarrow{NRL}$$

The components of $\overrightarrow{NRLB}$, $GMXBI$ and $GMYBI$, are included in the telemetry. The relative pointing of the S082B and S055A instruments was measured by coalignment, during which the step and line numbers were recorded for the S055A position which best coaligned the two instruments. Average coalignment step and line numbers for four different time periods are given in Table 1.2-I as well as average values of the S082B biases. The displacement from step S and line ℓ to the S082B pointing is:

$$\overrightarrow{DNH} = (S_{82} - S, \ell - \ell_{82}) \times 5''$$

where S_{82} and ℓ_{82} are coalignment step and line numbers. (The change in sign between the two components is caused by using a y -axis pointing upward and counting lines downward.)

In the γ_x, γ_y coordinate system the spectroheliometer is pointing toward:

NOTE: The solar axis is projected into the plane before measuring γ_{RR} from it.
 γ_x, γ_y and γ_{RR} are all positive in diagram.

Figure 1.2-A Pointing Coordinates

TABLE 1.2-I
AVERAGE VALUES OF POINTING OFFSETS

SL	DOYS	S082B coalignment error ± 1		S082B Bias arc-seconds	
		S_{82}	ℓ_{82}	XBIAS	YBIAS
2	143-218	32	8	$+55 \pm 10$	$+20 \pm 10$
3	218-330	32	9	$+55 \pm 5$	$+10 \pm 20$
4	331-346	32	10	$+50 \pm 5$	-25 ± 5
4	346-410	33	10	$+20 \pm 10$	$+80 \pm 20$

$$X_{HCO} = \gamma_x - GMXBI - (S_{82} - S) \times 5''$$

$$Y_{HCO} = \gamma_y - GMYBI - (\ell - \ell_{82}) \times 5''$$

where all quantities except step and line numbers are given in arc-seconds. This is accurate to ± 5 arc seconds if telemetered values are used for the biases. For greater accuracy see the Pointing Reference Handbook.

For a detailed illustration of the relationship between the Hydrogen Alpha photographs, the S055 pointing and data, and the S082B coalignment position, see the Data Handbook, section 2.3.

1.3 DATA RETRIEVAL SYSTEM

For a complete overview of the data retrieval system see the Data Handbook, section 4. Aspects relevant to the S055 data tapes are covered here.

The quantities used to generate the data tapes are listed in Table 1.3-I together with the number of bits transmitted and their sampling rates. Many quantities were packed into buffers which were divided into 10-bit words for transmission.

The real time data stream was termed ATM. In ATM sixty words were grouped into a frame; thirty frames into a master frame; sixty master frames into a master-master frame. Special synch words were included to mark the end of each frame and master frame. The data, structured in this way, were transmitted to the ground at 72000 bits per second; fifteen seconds were required to send an ATM master-master frame.

Since Skylab was not in contact with ground station for much of the time, many quantities, including all in Table 1.3-I, were recorded on board. The recorded data stream was termed ASAP (Auxiliary Storage and Playback). The recording telemetry was based on the same 10-bit words; however one hundred words were grouped into a frame and sixty frames into a master frame. The recording rate was 4000 bits/sec: fifteen seconds were required to record an ASAP master frame. The data were recorded on one of two recorders. A recorder could record continuously for 45 minutes. At this point two seconds of data would be lost

while reversing the tape. Another 45 minutes of data could then be recorded. The data could be dumped on ground command at 72000 bits/second: five minutes were needed for a complete dump of 90 minutes of data. (The orbital period was about 93 minutes.)

At a ground station the ATM data, and the ASAP data if any, and timing pulses were recorded on three tracks of magnetic tape. Simultaneously with this recording the ATM data was processed and transmitted. A time parameter generated from the timing pulses was inserted into the data stream.

After a station pass, the tape was rewound and the ATM data processed and transmitted again. Before transmitting the ATM data to Goddard Space Flight Center it was compressed: each 10 bit word was transmitted only if it differed from its last occurrence. Each transmitted word was accompanied by an identification code. The ATM data streams were received at Goddard and each continuous stream was called a batch. The batches were sent to Johnson Space Center where they were stored in the MDRS (Mission Data Retrieval System).

The magnetic tape at the station was rewound and the ASAP data were transmitted to GSFC. These data were not processed at the ground station and were only batched at GSFC. At JSC the ASAP batches were given GMT times by applying additive quantities (K-factors) to the on-board times contained in the data. The constructed GMT was monitored by comparing it to the GMT of coincident ATM batches.

Both kinds of data batches were read out of the MDRS and recorded on ADDT tapes (All Digital Data Tapes). The ADDT tapes were either transported or transmitted to Marshall Space Flight Center for processing.

1.4 SCIENTIFIC USER TAPE PROCESSING

Due to data transmission problems on the ground during the first part of the mission, it was decided to process data taken before day 275 from the ground station recordings of the transmissions from the satellite. This data base was termed "analog" to distinguish it from the ADDT data base. To speed up processing a group at JSC was given the data for days

Figure 1.4-A Schematic Timetable

197-202 and 234-290 to process from analog. This division is illustrated in Figure 1.4-A.

1.4.1 Preliminary Processing

Before any specific processing of the data could be done, the data had to be organized into a single stream. The data batches, whether ADDT or Analog, contained much redundant data. The times covered by ATM data were also covered by ASAP, unless the recorder was changing tape direction or was in playback. However ASAP contained only 1/18 of the total ATM data stream. Where station ranges overlapped ATM data, as well as ASAP, could be simultaneously received by more than one station, resulting in different batches containing identical data. Also a station might transmit the same data several times when communication problems existed or were suspected to exist. Each reception at each ground station resulted in another ADDT data batch.

The data were to be aligned by the time samples contained within the data stream. The onboard clock ran fast by about one second per three days and was reset periodically. More serious was the fact that the real time clock and the sampling times were asynchronous; sometimes there would be two clock updates or none per 0.25 second sampling period. Most serious was a noise problem which especially bothered the time readout.

The data were first aligned by data structure as described in Section 1.3. The special synch words marking the ATM master-master frame or the ASAP master frame were identified. Within the 15 second interval between these synch words data were kept only if there were no gaps before reaching one synch word, going either forward or backward. The time of the synch word was obtained after comparing adjacent time samples to eliminate noisy data. These synch words were then aligned at fixed 15 second intervals. The nearest such interval was considered to be the correct one, since this allowed for a discrepancy of up to 7.5 seconds while the asynchronous sampling and the resets introduced jumps of only .25 and 3 to 4 seconds respectively.

The GMT time in the merged data stream was generated in two different ways. JSC analyzed the behavior of the onboard clock and compiled a table of "K-factors", which are differences between GMT and the onboard

clock. The resulting GMT was to be accurate to less than a quarter second.

The time on the MSFC tapes was derived differently. The ATM batches contain a GMT obtained from WWV. The GMT on ASAP batches was derived by two different methods. For ADDT data a K-factor was applied when the data arrived. This K-factor had an accuracy of about 0.5 second. ASAP batches from analog were aligned with an ATM batch and the GMT's made to agree.

In deciding to use or continue to use a particular data batch or to look for the data in another batch, the three synch words occurring at the end of each frame were monitored for noise by MSFC. More than three erroneous bits would cause that frame to be rejected. Three consecutively rejected frames would terminate the processing of that batch. JSC used similar gates but also included the clock samples in the words to be checked when they were available.

1.4.2 Data Tape Generation

The actual format of the data tape is described in Section 2. We describe here some basic problems in handling the data and their resolution.

The instrument was considered to be on whenever any of the seven detector high voltages were higher than 2 KV. The data stream was broken up into files which were to be good approximations of usable data divisions. It was not required to format any segments with a duration of less than 5 seconds.

The data were to be considered in spectral mode unless the mirror was moving. The test for mirror motion is that both (a) the mirror mode is non-zero and (b) either S/EOR-EOL is on or XMIR is changing by 3 ± 1 steps every 250 milliseconds and is between 0 and 60 steps. The division between line scan and raster data was done solely on the basis of the mirror mode with a look-ahead check for consistency to minimize noise effects.

MSFC divided the data stream into three streams, one for each mode. The criteria described below were applied to each stream to divide it into files. The formatted files of data were then merged chronologically into a single stream which became the SUT.

JSC used the above criteria plus the appropriate criteria described below to divide a single data stream directly into consecutive files.

The mirror lines were defined as starting on the second zero S/EOR-EOL bit. This was checked for each line. The first line includes two zero S/EOR-EOL bits immediately before the first non-zero S/EOR-EOL bit of the file. The direction of the mirror was checked for the first line of a line scan file. If the motion was right-to-left, the data points were reversed and placed in the first line of the file; if the motion was left-to-right, the data were placed directly in the second line of the file and fill data were placed in the first line. Thus all even lines have left-to-right motion and odd lines, right-to-left. All odd lines have their data points reversed. A line-scan file can contain up to 60 lines at which point it is broken off and a new file started. Only S/EOR-EOL, X-POS, and MMODE are monitored.

The S/EOR-EOL bit is used identically in the raster. The line number, Y-POS, is monitored in the raster for proper storage of lines. All odd lines, which have a right-to-left scanning motion, are reversed before inserting the data into the file. A file can contain up to 60 lines which constitutes a complete raster.

All data for which the mirror is not regularly scanning are formatted as spectral. To break these data into usable portions in which either the data are true spectral with the grating moving or are stop data giving high temporal resolution (42 ms) at one point (5" x 5"), the following rules were adopted.

1. All data were stored by time, filling any gaps which might exist.
2. The decision to stop processing of a data file and start another file was made under one of two sets of rules which were called STOP and GRAT termination modes. STOP mode was assumed at the start of processing of a data file. Under certain conditions, STOP changed to GRAT, but could not return to STOP within that file.
3. The two times defined below were used in decisions.
 - a. ΔT_S is the time since the last valid grating motion or since the start of processing of the file.
 - b. ΔT_G is the time since the grating started moving

with a valid slope. A valid slope is one in the range 3 to 24 steps per second.

4. STOP changed to GRAT if both the following conditions were met:
 - a. When the grating started moving ΔT_S was less than or equal to T_{MS} , and
 - b. Valid grating motion continued until ΔT_G was greater than T_{MG} . T_{MS} and T_{MG} were given the values of 16 and 43 seconds.
5. A file being processed in STOP termination mode terminated if either:
 - a. Valid grating motion occurred when ΔT_S was greater than T_{MS} , or
 - b. 6012 data points had been collected, including any fill data.
6. A file being processed in GRAT termination mode terminated if any of the following occurred.
 - a. A grating step decreased to a step number less than 24;
 - b. An invalid slope lasted for a time ΔT_S greater than T_{MS} ; or
 - c. The number of points stored reached 6012.
7. Since optical reference occurs after about 104 steps of the spectrum are passed, the last 120 steps of one scan were sometimes inserted before the first point of the next scan. If the processing in termination mode GRAT ends due to both:
 - a. A decrease in step number to a value less than or equal to 24, and
 - b. The step number of the last (highest) step is greater than or equal to 5460,
 then the last 120 points and the time of the last step were saved.
 The 120 saved points were added to the start of a scan if both:
 - i. The first grating position was less than or equal to 24 and
 - ii. The time since the last point of the 120 was less than 3.5 min.
8. Gaps in data were bridged in STOP mode if the gap could be contained in 6012 positions. In GRAT mode a gap is bridged if

all the following held:

- a. The bridging could be done within the 6012 data points allowed;
- b. The change in grating step was positive; and
- c. The length of the gap is less than or equal to the change in grating step during the gap multiplied by 42 milliseconds plus T_{MS} .

The major problem again was time. Since the scientific data records do not contain time but only sequential data points, a rigid time rate was required through each file. This was achieved by constructing time within each file starting with the GMT of the first data point. Because problem areas in the data sometimes exhibit apparent time jumps, the GMT as derived by the methods mentioned in Section 1.4.1 was included as an engineering data item.

The engineering data were to be sampled once within each second, except for S/EOR-EOL, OR and MR. To make the data as useful as possible the time associated with a sampling of the engineering data was to be the time when the fastest changing quantity was sampled. Thus for mirror modes the time is that associated with XMIR; while for spectral data it is that associated with the grating position. The ATM pointing data which were sampled about every 15 seconds were repeated until new values arrived.

2. DATA TAPE STRUCTURE

To allow easier use of the data some sections of this chapter are in quasi-tabular form.

2.1 TAPE STRUCTURE

Density: 556 bpi

Parity: Odd

The micro-structure of the seven track tape is based on the CDC word of 60 bits. All descriptions are in terms of this word size. The macro-structure is a series of files, each terminated by an end-of-file mark. The tape is terminated by a double end-of-file. The files are arranged chronologically on the tape and are numbered consecutively.

2.2 FILE STRUCTURE

Each file consists of records in the following order:

<u>Name</u>	<u>Number</u>	<u>Length (Words)</u>	
ID	1	18	labels data
ENG1	1 to 3	486	12 engineering measurements sampled once per second
ENG2	1 to 24	336	3 engineering bits sampled 24 times per second
Scientific	1 to 30	Spect. 501 Raster 495 Line 462	All scientific records in one file are the same format. There are three possible formats depending on the instrument operation.

2.3 RECORD STRUCTURE

2.3.1 ID RECORD

The ID record is 18 words long and each word contains a single

integer. A detailed description is given in Table 2.3-I.

2.3.2 ENGI Records

Each ENGI record is 486 words long, consisting of up to 121 blocks of 4 words and followed by at least 2 words of terminal fill. (JSC uses all bits on for terminal fill while MSFC uses all bits off). The 4 word blocks consist of a sample time in milliseconds and samples of 12 engineering measurements. The engineering data are packed in 15-bit segments, four per word. The space remaining after the engineering data is stored is filled with terminal fill. MSFC always produces three ENGI records; any unused records contain zeroes.

Each 4 word block is structured:

Word	high order		low order	
1	milliseconds			
2	GAMY	GAMX	GMXBI	GMYBI
3	GMT	X-POS	Y-POS	GAMRR
4	GRTPOS	MIRR	GRAT	REFSEL

Each 15-bit segment (except (GMT) is structured:

bit numbers:	14	13	12	----	0
use:	flag	sign	magnitude.		

When a datum is missing the flag bit along with all the rest of the bits is turned on. The values in the field have to be multiplied by a scaling factor to obtain the values in the units used. The data are described in Table 2.3-III.

When a gap occurs in the data MSFC will not process times within the gap. This results in the stored time suddenly jumping forward. JSC will supply times within the gap but will treat all data as missing.

TABLE 2.3-I
CONTENTS OF ID RECORD

<u>WORD</u>	<u>DESCRIPTION</u>
1.	Tape number - Let <u>a</u> be the DOY in three digits, <u>b</u> be one digit representing the quarter of the day, and <u>c</u> and <u>c'</u> be single digit indices starting at one. MSFC uses five digit tape numbers: <u>abc</u> . JSC uses four digit tape numbers normally: <u>ac</u> ; and five digit numbers for reruns: <u>acc'</u> .
2.	File number
3.	MSFC: Site code (Table 2.3-II) JSC: SL number *10 ⁶ + day/night cycle number.
4.	Year = 1973
5.	Day number-1973: Day of year (DOY); 1974: Day of year +365 (consecutive from 1973 DOY's).
6.	GMT of "start" point in milliseconds.
7-13.	Each contains 0 or 1 depending on whether detector 1-7 was off or on; e.g. if detector 2 was on at any time during the file, word 8 contains a 1.
14.	Storage mode - This indicates the type of data and the type of scientific record used depending on mirror motion: 0 - mirror not moving; spectral data. 1 or 3 - mirror is rastering. 2 - mirror is line-scanning.
15.	Total number of engineering records, both ENG1 and ENG2.
16.	Total number of scientific records.
17.	"Start" point - This is a pointer to the scientific data point whose time is given in word 6. The value given here is the index which the base data point would have if all the points in the scientific records were put in their original time sequence and the first point numbered one. (When the mirror is moving the data are not stored in strict time sequence.)
18.	Not used.

TABLE 2.3-III

CONTENTS OF ENGI RECORDS

<u>WORD</u>	<u>NAME</u>	<u>SCALING FACTOR</u>	<u>UNITS</u>	<u>COMMENTS</u>
1	time	1	milliseconds	Time of day. This time is generated within each file to insure a constant rate. The raw GMT is given as a data item.
2	GAMY	1*	arc-seconds	(also FSSUD) Y displacement of FSS from center of sun.
	GAMX	1*	arc-seconds	(also FSSLR) X displacement of FSS from center of sun.
	GMXBI	1*	arc-seconds	X-bias for S082 from FSS.
	GMYBI	1*	arc-seconds	Y-bias for S082 from FSS.
3	GMT	1	milliseconds	This is the GMT from the telemetry stream modulo 30000. All 15 bits are used for data.
	XPOS	.01	X-units	An X-unit is about 5.0 arc seconds. The center of a line is approximately at 31.5 X-units.
	YPOS	.01	line number	The lines are counted downward. The line number is an analog measurement biased by .5 so that the true line is gotten by truncation. Consecutive lines are separated by approximately 5.0 arc-seconds.
	GAMRR	4/3*	arc- minutes	Clockwise rotation of cannister prior to displacement.

*These scaling factors are nominal pending a detailed analysis of the pointing.

<u>WORD</u>	<u>NAME</u>	<u>SCALING FACTOR</u>	<u>UNITS</u>	<u>COMMENTS</u>
4	GRTPOS	1	grating steps	This is incremented by 1 for each step that the grating cam is moved. A step is approximately .21 Å for all detectors. GRAT is reset to zero whenever either: 1) Optical reference is selected and comes on, 2) Mechanical reference is selected and comes on, or 3) The counter overflows after step 8191.
	MIRR	1	mirror code	This is a two bit quantity with the following interpretations: 0 STP - no mirror motion. 1 M3R - mirror does three rasters and then stops. 2 MLS - mirror scans back and forth on same raster line. 3 MAR - mirror rasters continually until stopped.
	GRAT	1	grating code	This is a three bit quantity with the following interpretations: 0 STP - no grating motion. 1 GAS - grating scans continually until stopped. 2 G3S - grating does three scans then stops. 3 REF - grating moves until a reset occurs. 4 SS - grating moves only a single step when started. 5 } illegal values (may be generated by noise) 6 7
	REFSEL	1	select code	This is a one bit quantity indicating which grating reference is to be used: 0 = mechanical reference 1 = optical reference

JSC sampled the data stream at nearly one second intervals for ENG1 data. MSFC sampled once within each second but not necessarily at fixed intervals. In both cases the sampling time should be that of the GRAT sample for spectral data and that of the XMIR sample when the mirror is moving. Correlation with the scientific data should be done using the time and parameters 6 and 17 in the ID record. (See section 3.1.2).

2.3.3 ENG2 Records

Each ENG2 record is 336 words long, each word containing three single bit measurements and their time. The space remaining after the engineering data is stored contains terminal fill: all bits on (1) at JSC: all bits off (0) at MSFC. MSFC always produces maximum records needed; any unused records contain zeroes.

Gaps in the data are treated as for ENG1 data; i.e. MSFC times jump forward, JSC supplies missing times and flags data as missing.

The ENG2 data are sampled 24 times per second and have a one-to-one correlation with the scientific data.

Each word is structured (high to low order):

30 bits	10 bits	10 bits	10 bits
time	Optical	End of raster/	Mechanical
milliseconds	Reference	End of line	Reference

The time is taken from the generated time. If a datum is missing all bits within a 10-bit quantity are turned on. Each 10-bit quantity contains a single bit of engineering data. The optical reference point is the first occurrence of the corresponding bit. The mechanical reference point is similarly defined. Depending on the reference selected, it is at this point that the step counter is set to zero. The optical reference bit remains on for about 35 steps. The mechanical reference remains on for about 600 steps. The optical reference occurs 104 ± 3 steps after the mechanical reference. The end-of-raster/end-of-line bit is on while the mirror is scanning a horizontal line. It goes off for three samples at the end of a line; the second of which is considered to be the first sample of the next line. This bit is off when the mirror is not moving from or

going to the neutral position at the beginning or end of a raster or set of line scans.

2.3.4 SCIENTIFIC RECORDS

The structure of these records has little flexibility so that a correlation may be made with the engineering records using only parameters 6 and 17 in the ID record. Each word has 4 measurements packed from high to low order. If a measurement is missing, for any reason, the place is flagged by setting all of the fifteen bits on.

Fill data used to fill out a record are similarly flagged. (When MSFC produces the maximum number of records, any unused records contain fill data.)

Each data item is contained in 15 bits as follows:

1 bit	14 bits
flag	count

The count is the detector counter read-out. The flag bit is set if the high voltage for that detector appears to be less than one half of the operational voltage. Due to non-synchronization in the sampling and finite voltage rise and fall times the setting of this bit does not correspond very accurately to the loss of sensitivity of that detector.

2.3.4.1 Spectral Data (Mirror not moving): ID (14) = 0

The data are put in this form whenever the mirror mode bits are off or the mirror is not moving. Each record contains 501 words or 2004 data items. The data are stored consecutively after being ordered by detector. Each detector which was on during the time interval has N records; N being between 1 and 3. The number of scientific records is N times the number of detectors on. Since the maximum number of records per detector is fixed at 3, the maximum number of data points is 6012 and the maximum time span is 250.5 seconds. The files are also divided whenever a reset occurs after more than 43 seconds of grating motion. On most such occasions the 120 data points preceeding the reset will be carried over to the new file. This is indicated by ID (17) containing 121, pointing to the 121st

point as the base point in the file. This carry over allows the data between mechanical reference and optical reference to be easily used as the start of the spectrum even when reset occurs at optical reference.

2.3.4.2 Raster Data: ID (14) = 1 or 3

The data for each detector are put into a raster array of 132 by 60. Each record contains 495 words or 15 lines of 132 points each. Each detector which was on has N records; N being between 1 and 4. For each detector the first record contains lines 1 through 15, etc. MSFC always has N equal to 4; JSC will use N less than 4 if the raster was cut off before line 46. Any unused data items are filled with all bits on.

The raster is assumed to start on the second zero before the S/EOR-EOL bit goes on. Each line is started on the second of three zeroes in the S/EOR-EOL bit. The raster is assumed to end when 16 consecutive S/EOR-EOL zeroes have been found. (A raster file may also be ended when anomalous mirror motion is found due to noise or other difficulties.)

The mirror scans odd lines in a right-to-left direction. The data points in these lines are reversed before writing the data on the tape. However ID (17) is calculated chronologically; thus ID (17) = 1 indicates the first point which is the rightmost point of the first line or the 132nd point in the array, while ID (17) = 133 indicates the leftmost point of the second line or the 133rd point in the array.

Frequently when a raster is ended prematurely, the last sixteen data points stored were taken after the mirror stopped rastering and while it was returning to its stow position.

2.3.4.3 Line Scan Data: ID (14) = 2

Each record contains 462 words. The data is divided into detectors and lines as follows:

Words	Detector	Mirror Moving
1 - 33	1	right-to-left
34 - 66	2	
67 - 99	3	
100 - 132	4	
133 - 165	5	
166 - 198	6	
199 - 231	7	
232 - 264	1	left-to-right
265 - 297	2	
298 - 330	3	
331 - 363	4	
364 - 396	5	
397 - 429	6	
430 - 462	7	

If a detector is not on, fill data are stored. The maximum number of lines per file is 60: therefore there are up to 30 scientific records in a line-scan file.

The data are synchronized with the mirror motion using the S/EOR-EOL bit as described under Raster Data. Similarly the data points in right-to-left lines are reversed before writing the data on tape.

When a line scan ends, the last sixteen data points are usually recorded after the mirror stopped scanning and while it was returning to its stow position.

3. DATA PROBLEMS AND DIAGNOSTIC TECHNIQUES

The list of items below is not intended to be exhaustive but to provide starting points in the handling of imperfect data. Some information on the use of engineering data is also included in this section.

3.1 TIME

3.1.1 Accuracy and Use of GMT Engineering Data

The overall accuracy of the constructed time is of the order of a half-second. This error size is for the ADDT-ASAP data. All other data sources should have accuracies of the order of a quarter-second or better. These accuracies are estimated on the basis of the handling of good data.

Since the times within a file are constructed from the time of the "starting" data point, a noise hit on that time could cause the entire file to have erroneous times. Large errors are usually caught in processing. Small errors can be found through the use of the GMT engineering data.

By comparing the raw GMT with the constructed GMT, noise hits can be found. A direct comparison will frequently show the clock drift as well as the small jumps due to the causes mentioned in Section 1.4.1. If a noise hit affected the starting time of the file, the GMT will show a jump when it returns to good values and then should settle down. If the GMT exhibits jumps relative to the constructed time throughout the file, the data may be expected to be very noisy also. On rare occasions this could mean a bad merging of two data batches.

3.1.2 Correlation of Scientific and Engineering Data

This is done entirely through the time constructed within a file. The scientific data from any one detector is to be organized into a time sequence; i.e. for raster and line scan data reverse the odd rows. The n^{th} data point is the starting point, where n is the value in word 17 of the ID record. The time of this point in milliseconds is in word 6 of the ID record. Each data point is 1/24 second later than the preceding one.

These times should be within two milliseconds of the times given in the ENG2 records. The ENG1 times should represent the sampling time of XMIR for mirror modes and GRAT when the mirror is not moving. MSFC used the data point time closest to the sampling time while JSC evaluated the

actual sampling time. Thus on MSFC tapes each ENG1 time corresponds to an ENG2 time while on JSC tapes each ENG1 time occurs a few milliseconds later than ENG2 time.

3.1.3 Time Gaps

If a gap occurs in the usable data stream for any reason (e.g. instrument was turned off then on; bad telemetry) and the instrument mode was not changed, the gap was to be bridged using fill scientific data if this could be done within one file. Otherwise the file was to be stopped where the data ended and a new file commenced where the data resumed.

There are gaps of about 3 seconds between sequential rasters. A rapid sequence of mode changes by the astronaut in setting up some observation may cause a gap due to not keeping files shorter than 5 seconds.

3.1.4 Mode Change Timing

When a mirror mode is stopped by command, in the last line are included about 16 data points which were taken while the mirror was moving to its stow position. The purpose of including these points was to allow noise and anomalous situations. The points taken after the mirror left its scan pattern can be identified by having zero S/EOR-EOL bits associated with them.

3.1.5 High Voltage Timing

The high voltage was sampled once per second in the ASAP data stream and 4 times per second in ATM. When the high voltage was off the data was flagged or not processed at all. Due to the low sampling rate, particularly in ASAP, the scientific data can be observed to fall or rise before the flag appears or is removed.

3.1.6 Calendar Peculiarities

MSFC numbers the DOY's continuously through to the end of the mission. Thus they are all treated as DOY's of 1973. DOY's in 1974 correspond to the number in word 5 of the ID record when 365 is added to them.

At the end of a day MSFC continues time sequentially until the end of the tape resulting in times greater than 86,400,000 milliseconds (24 hours).

3.2 NOISE

Noise can arise from either a poor transmission from Skylab to a ground station or from problems in handling the data on the ground. The earlier data were quite noisy.

3.2.1 Frozen Data

This is a data problem which frequently manifested itself as an anomalous data value which persisted for several seconds. It was caused by faulty ground transmission of compressed ADDT/ATM data. Due to the compression scheme (Sec. 1.3), noise introduced into the data stream between the ground station and the final ADDT tape could be interpreted as an update to a data value which was then left uncorrected until the next legitimate update. Since the transmitted quantities were 10-bit words, this could affect sections of the detector counts or the grating position instead of the entire measurement.

A related phenomena was an unmarked data drop-out in an ADDT/ATM batch often after some noise. This resulted in every quantity in the data stream retaining a fixed value for several seconds.

There should be very few examples of this problem due to the choice of data batches and the monitoring of the final data tapes.

3.2.2 Data Spikes

A single noise hit on a data point frequently results in an anomalously high (or low) count. This is termed a spike. The onset of noise in the data stream may result in several obviously bad data points before the stream becomes too noisy to process.

3.2.3 High Voltage Noise

If the high voltage is hit when on, it may result in the high voltage off flag appearing for 6 to 24 data points.

If the high voltage is hit when off, the data points may appear

usable. If another detector is on, 6 to 24 (usually noisy) data points appear as the sole "detector on" points for that detector in the file. If all detectors are off when the hit occurs, the data is usually ignored as too short to be useful. However if two hits occur within a file length of each other, the data processor will attempt to bridge the gap. If it is successful a file will be created consisting of several noisy data points.

3.2.4 Line Number Noise

Noise in the YMIR quantity during a raster can cause the program to store the line improperly. If the next line number is smaller than the last, the current file is ended and a new one started. If the line number jumps up, the next line is stored at the high line number and XMIR is more closely monitored. A continued sequence from the high value or a set of non-sequential values will result in the lines being stored consecutively. A drop in YMIR and a subsequent sequence will cause the current file to be terminated.

Line number noise does not affect the processing of line scan or spectral data.

3.2.5 Mirror Mode Noise

Due to the checks on mirror motion, noise in the MMODE bits will not affect spectral data unless there is also noise in XMIR and/or S/EOR-EOL. Noise in the mirror mode while processing data in one of the mirror modes may misclassify the data in spite of the consistency check. This data would probably be lost unless there was enough to produce a file of greater than five seconds. The file being processed would have a gap on an MSFC tape. The JSC processor would end the file and start a new one.

3.2.6 Power Transient Anomaly

A power transient on unmanned day 277 caused instrument anomalies. Outside of greater care in instrument operations, the main result visible in the final data was the change of the mirror stow position to line 0, step 30. It remained there until the incoming SL-4 crew reset the stow position. Further discussion of this anomaly is in the Data Handbook section 3.6.2.

3.3 PROCESSING DIFFERENCES AND PECULIARITIES

3.3.1 Parallel Vs. Serial Processing

JSC processes the data serially; i.e. a single data stream is used and a single pass is made along it. Thus any mode changes will stop the processing of the present file and will output it before proceeding. Serial processing has the advantage that a following file always has data from a later time than a preceding file, except in the case of 120-point spectral carryover.

MSFC divides the data into three streams and processes them in parallel before merging them into a single data tape. This has the advantage that noise bits frequently only cause gaps rather than new files. However either noise or rapid switching can produce two or three files where the data in one file fills the gaps of another. These files would be ordered chronologically by the times in the ID record when merged for the SUT.

3.3.2 Word 3 of the ID Record

MSFC and JSC put different quantities in this word.

3.3.3 Number of Engineering and Scientific Records

JSC uses as many records as are needed to hold the data. MSFC uses fixed numbers of records depending on the data type.

3.3.4 Gaps in Engineering Data

When a bridgable gap occurs in the data stream, JSC constructs time across the gap but flags all the data as fill. MSFC jumps the time forward to where data exists.

Often when an unbridgable gap is discovered, MSFC will already have processed some engineering data. This data will appear at the end of the engineering records. The scientific data will not be processed and the engineering data will be reprocessed at the appropriate place.

3.3.5 Organization of Data onto Tape

JSC proceeded through the data they were assigned, changing tapes

when the end of the present tape was sensed. The tapes were numbered serially within the days in which they started but a tape may contain data from more than one day. If a rerun was required the data corresponding to an entire tape was processed. If the rerun was longer than the original, the overflow was put on a separate tape.

MSFC did all of its processing in quarter-day batches. The maximum number of files on a tape was fixed at 70. The tapes were numbered by the day, the batch, then serially within a batch. This method of processing resulted in more tapes per day than that of JSC, but the data is easily identifiable by quarter-day.

3.4 INSTRUMENTAL DATA PROBLEMS

These problems were caused by the instrument or the way in which it was operated.

3.4.1 Detector Counter "Overflow"

The detector counters on the instrument were 16-bit accumulators but the highest two bits were not telemetered. Thus the largest onboard count was 65535 but the highest telemetered count is 16383.

The best way of handling the data is to consider the instrument to have had 14-bit counters which continue to increment past overflow. Strong lines, e.g. $\text{Ly}\alpha$ in an active region, may cause multiple overflows.

3.4.2 Non-Started Mode

Until the instrument is started by a separate command, the mirror remains stationary even if a mirror mode has been selected. All of the data taken while the astronaut is setting up the instrument is often put in one file. The engineering data of this file may show several different mirror and grating modes but no mirror motion. Such a file is classified and treated as spectral.

3.4.3 Night Data

The instrument has provision for the automatic closing of the door during the night part of the orbit and for automatic turning off of

the high voltages when the door is closed. For many orbits the instrument was operated with overrides annulling these automatic features resulting in files of dark count data.

3.4.4 Trip-Outs

A large pulse in the high-voltage of one detector would automatically turn all the detectors' high-voltages off. During manned operations the crew, warned by a red light, would quickly reset the detectors; this results in the loss of a small section of the data set being collected, e.g. the raster or the spectral scan. During unmanned or unattended operations the discovery of the problem and the subsequent reset had to wait for a station pass; this may result in the loss of a sizeable section of the desired data. During the manned part of the SL-3 mission, detector 5 was found to be the principal culprit and was left off during most of the remaining time. The history of the problem is given in the Data Handbook, section 3.6.2.

3.4.5 Alignment of Successive Scans

The positions of points on each mirror line are determined by the behavior of the mirror at the start of the line. Thus right-to-left (odd) lines are aligned as are left-to-right (even) lines. Even after the data points of the odd lines have been reversed the two sets of points are not aligned; the points on the even lines being about .4 of the distance between points to the right of corresponding points on the odd lines.

The data have been formatted with the odd lines reversed. The odd-even shift should be applied to both line scan and raster data when desired.

3.4.6 S/EOR-EOL at Start of MLS

The S/EOR-EOL bit often came on before the mirror started the first line at the beginning of a line scan sequence. This results in line one being fill data since the mirror is moving to the right at that time and the data is to be put into an even line. This partial line of data will usually not be stored at the end of line 2 but at the start. The third line of the file should be properly stored and is the data the file would normally start with.

3.4.7 Line Stepping in MLS

It is possible for the astronaut to change the line by a step at a time while the instrument is line scanning. Such changes will not cause the file to be divided; they can be detected using the engineering data.

3.4.8 Grating Overflow

The grating position counter could be reset either by mechanical or optical reference. When optical reference was selected but insufficient light was entering the instrument (e.g. off-limb or night data), the reset did not occur. In such a case the counter continued to 8191 and then overflowed to 0. If such data are used the location of mechanical reference can be found in the engineering records.

3.4.9 Grating Reset Anomaly and Step-Loss

The grating counter should be reset to 0. Under certain timing conditions the reset was to 1.

The grating counter occasionally slips back one step. This is most easily seen when the grating was stopped at reference and was reset to 1. After a time, possibly many minutes, the grating counter may go to zero. On a few occasions 23 counting steps were noted within one second during a grating scan.

3.4.10 Grating Position Variations

The relation between step number and wavelength is linear only to an accuracy of about 1 Å. For greater accuracy not only must the anomalies in the shape of a cam be accounted for but also that there are non-linearities which recur about every 8 spectral scans. For further information see the Data Handbook.

3.4.11 Aperture Door Malfunction

This could have developed into a serious problem. Since its effects were in the ability to take the data and not in the data storage or processing, this will not be described here. The Data Handbook, section 3.6.2 details the malfunction, its occurrences, and its solution.

3.5 POINTING PROBLEMS

3.5.1 Pointing Sampling Rate

The cannister pointing data was sampled about every 15 seconds. The last data value was repeated in the engineering records until a new sample arrived. When the cannister is being repointed with S055 on only the initial occurrence of each value should be used.

3.5.2 General Pointing Difficulties

As mentioned in Section 1.2 there are problems with interpreting the pointing to an accuracy of greater than ± 5 arc seconds. The roll angle has an error of about 5 arc minutes during manned periods and as much as 5° during unmanned. For a full description see the Pointing Handbook.
