Table of Contents

---

1. INTRODUCTION:

The documentation for this data set was originally on paper, kept in NSSDC's Data Set Catalogs (DSCs). The paper documentation in the Data Set Catalogs have been made into digital images, and then collected into a single PDF file for each Data Set Catalog. The inventory information in these DSCs is current as of July 1, 2004. This inventory information is now no longer maintained in the DSCs, but is now managed in the inventory part of the NSSDC information system. The information existing in the DSCs is now not needed for locating the data files, but we did not remove that inventory information.

The offline tape datasets have now been migrated from the original magnetic tape to Archival Information Packages (AIP's).

A prior restoration may have been done on data sets, if a requestor of this data set has questions; they should send an inquiry to the request office to see if additional information exists.

2. ERRATA/CHANGE LOG:

NOTE: Changes are made in a text box, and will show up that way when displayed on screen with a PDF reader.

When printing, special settings may be required to make the text box appear on the printed output.

MERGED X-RAY DATA

75-057A-03A SOXR-00065

This data set has been restored. There was originally 370 Binary 9-Track, 1600 BPI tapes. There are 92 restored tapes. The DR and DS tapes are 9-track, 6250 BPI. The tapes were created on an IBM 360 computer. The DR and DS numbers along with the corresponding D numbers and the time spans are as follows:

DR#	DS#	D#	FILES	TIME SPAN
DR01081	DS01081	D31774	1-5	06/30/75 - 07/03/75

MERGED X-RAY DATA

75-057A-03A

This data set catalog contains 370 Magnetic tapes. They are 9 track, Binary, 1600 BPI with multiple files. These tapes were created on an IBM 360 computer. The tapes have 3 files of data on each tape unless it is otherwise noted in the following listing. The dates are not necessarily in sequential order on the tape but the dates do reflect the total time span covered by that tape.

D#	C#	# of FILES	TIME SPAN

CALOO

ABSTRACT

CALOO is primarily a FORTRAN IV computer program, written to execute on the IBM 360/65 at MD&O (Bldg. 14) at GSFC. The program reads input data tapes received from IPD at GSFC containing OSO-8 satellite data for experimenter number 5. Output data tapes and computer printouts are created. The output tapes contain the original data in a re-organized fashion, such that it is more easily accessible for further analysis. The printed output summarizes the housekeeping of the experiment so that the experimenter may easily determine the status of the instrument's operation at any given time.

HISTORY

CALOO was written in the fall of 1975 at COLUMBIA ASTROPHYSICS LAB. by Dori Miller. The program was taken to GSFC for debugging and testing. It was installed on disk and put into production mode when data tapes were received in February 1976. Several minor modifications were made between February and April 1976. A notebook describing these modifications is located in Room 1012 at COLUMBIA ASTROPHYSICS LAB. The current executing version is CALOO.04. It is compiled under FØRTRAN, PARAM = XL.

INTRODUCTION

Data tapes containing label information, orbital information and OSO-8 science data for experimenter number 5, are prepared by IPD at Goddard Space Flight Center, Greenbelt, Maryland, and released to The Columbia Astrophysics Lab., for further processing.

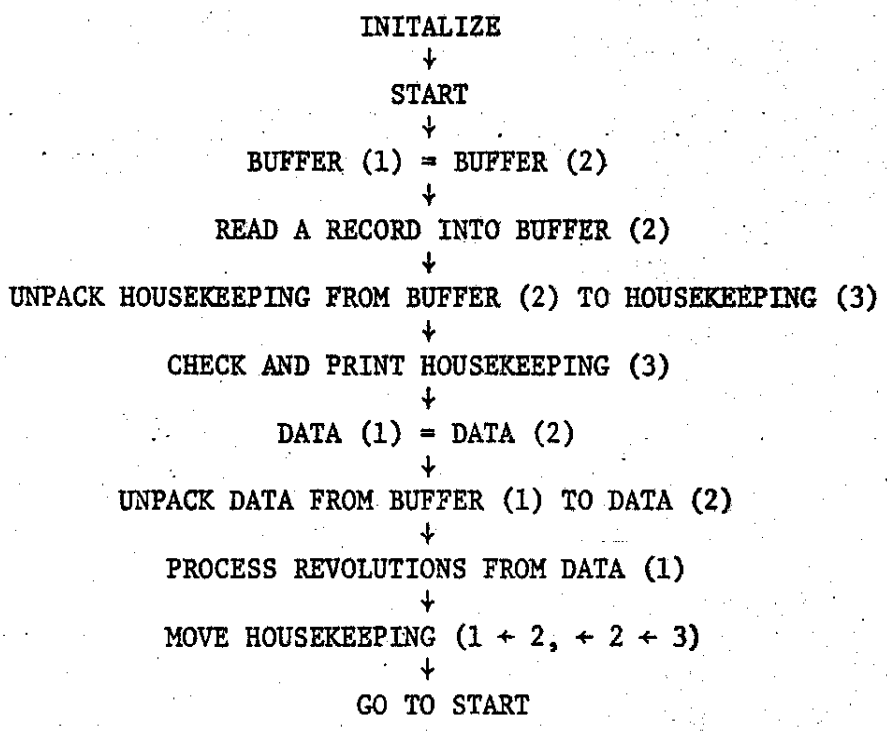
Each data tape contains approximately 24 hour's worth of data. There are a variable number of files on each tape (usually between 15 and 22) and the end of the tape is signified by two end of file marks. It is assumed that both the files and the data contained in a file on the tape are contiguous in time.

Each file begins with one label record, followed by a variable number of orbital data records, followed by a variable number of experimental data records. A description of the label record format is found in Table 5, and the orbital record format is described in the section SUBROUTINE OBIT, and Table 6.

Each experimental data record represents one MAJOR FRAME of data. This is a spacecraft dependent time unit and is equal to 20.48 seconds of real time. Table 16 shows the experimental data record format, as supplied to C.A.L. by IPD.

The remainder of this document describes how the data tapes are read and processed.

GENERAL PROGRAM LOGIC



PROGRAM STRUCTURE

CALOO consists of a main program, and nine subroutines all written in FORTRAN IV. There are six additional routines used for I/O and bit manipulation that are provided in-line at MD&O. There are two 360 assembly language routines included in the deck also for bit manipulation. A summary of the program structure is included in Table 1. A detailed description of each program segment follows.

MAIN PROGRAM

The main program of CALOO is essentially a driver routine that calls subroutines in the proper order for processing one data tape.

The first section of code initializes counters that tell total tape quality and reads in the NAMELIST. (NAMELIST items are described in table 2; counters are described in table 3). The input tape is mounted on unit NTAP at file NFIL.

The next section initializes counters for each file, and positions the input tape to the proper file.

The main body of the program reads the input tape and calls subroutines, performing what is described in "GENERAL PROGRAM LOGIC".

The final section of the code takes into account error conditions on the input tape, prints out summary information for each file processed, as well as summary information for the total run. (Explanation of printed summary information is contained in tables 3 and 4).

SUBROUTINE LABEL (IBAD)

When a record type =1 is read from the input tape, the main program calls SUBROUTINE LABEL. The first input record of each file should be type 1. This routine prints out selected information from the label record. TABLE 5 describes the label record. It is taken from the document OSO-I PRODUCTION DATA FORMAT FOR CAL X-RAY SPECTROMETER AND POLARIMETER EXPERIMENT #5. Items that are starred are printed.

"IBAD", the parameter returned to MAIN is set to =0 if this is our experiment (experiment #5) and set to =1 if this is not our experiment. If IBAD=1, a message is printed by subroutine label, and when control returns to MAIN, all processing stops.

SUBROUTINE OBIT (IREC)

When a record type =2 is read from the input tape, the main program calls subroutine OBIT. The purpose of this routine is to collect orbital information which is given once per min, for later interpolation so that orbital information can be attached to each revolution record.

Each orbital record read contains up to 26 blocks of 20 parameters each. There are a variable number of orbital records in each file; however, they occur consecutively and appear after the label record and before the science data records. CALOO saves 14 of the 20 available parameters, and allows for up to 250 blocks. The saving sequence ends when the first parameter of a block is equal to 88888888. The first word of each orbital record contains the record type indicator, the next 8 words (all "words" in the orbit records are IBM double precision) are fill, such that the blocking sequencing starts with the tenth word of the record.

IREC is a record counter passed from MAIN to OBIT. It is used to flag the start of a new file, so that the counter NOB which indicates the number of orbit record collected can be reset to zero.

Table 6 describes the 20 parameters in the orbital records indicating which are saved and the array location of the saved parameters. The saved parameters are passed in array X(14,250) in CØMMØN/IØBBLK/.

If more than 250 blocks of orbital data are found in a file, a message is printed once for each record thereafter. No more than the first 250 are collected; however, processing continues.

SUBROUTINE HKUPK (NFILL, NBMF)

Every time an experimental data record (ITYP=3) is read by MAIN, this subroutine is called. The data record is read by MAIN into IBUF(i,2) and passed in COMMON/IBBL/IBUF (1080,2) to HKUPK. This subroutine unpacks the housekeeping data into the array IHK (i,3), where i can range 1 - 60.

The subroutine is set up as follows: First, the array IHK (i,3) is set equal to the missing code. Next, in a loop going from 1, NPAR, each relevant minor frame is examined. The array NMF, which is set in a data statement, defines which minor frames are to be considered. If the flag field for a minor frame indicates error bits, the unpacking of that minor frame is bypassed, leaving the related IHK item set to the missing code, and incrementing the counter NFILL*. If the minor frame number in the data stream does not agree with the expected minor frame number the unpacking is bypassed and the counter NBMF* is incremented. Otherwise a GØ TØ (, , . . .), K statement defines which section of the code is to be used to unpack the data. Table 7 indicates the indexing used for the unpacking, and Table 14 shows which bits are used and any conversions necessary to obtain the final relevant IHK items.

Last, when the unpacking is completed, the preamp status (off or on) are combined as defined in Table 14, "reference" is determined as shown in Table 9, "status" is determined as shown in Table 8 and rates are decoded as shown in Table 9. Control is then returned to MAIN.

*See Table 3

SUBROUTINE HKPRNT (IREC)

For every experimental data record read, MAIN calls subroutine HKPRNT immediately after calling HKUPK. IREC, the passed parameter is a counter initalized for each file, of the number of experimental data records read (i.e. major frame number).

This subroutine always prints housekeeping from the first 5 major frames and the last major frame of each file. Other major frames are printed if any one of certain housekeeping items change by more than an input limit from the "standard frame". (described below). Table 3 indicates which items are checked and Table 14 shows which items are printed.

If IREC =1, (the first major frame of a file), constants are set and an array of the "standard frame values" is set to missing. Then, for all frames an array of trigger indicators is set to the alphanumeric blank. In a loop, each significant item is checked against the "standard frame's" item. If this item differs from the previous by strictly more than that item's limits a counter (NBAD) is incremented and the appropriate item of the trigger indicator array is set to the alphanumeric '*'. If the item or the "previous item" is missing the check is not performed, however, if the "standard frame" value is missing and the frame item is non-missing, the standard is set to this item.

Next the "z" check is performed. The right ascension and declination of the spin axis are saved from the first record of each file. The quantity Z is computed:

if RA1 = saved right ascension

DE1 = saved declination

RA = this right ascension

DE = this declination

then Z = sin (DE) *sin(DE1)+cos(DE)*cos(DE1)

*cos(RA-RA1)

SUBROUTINE HKPRNT (IREC) CONTD.

The limit for Z variance from the previous Z is .99999048 (i.e. 114°). If Z varies by more than this amount and Z is less than .99999048, a print is triggered, and RA1 and DE1 are reset to RA1=RA, DE1=DE.

Next, if this is not the first 5 frames or the last frame and no print trigger has been set, control returns to Main. Otherwise time is converted from milliseconds to hour, min, secs, the second line for printing is stored and the first line is printed. If this is the last record of the file, or the line counter has reached 60, the array of "second line" data is printed.

Last, when a print has been triggered the "standard frame values" are set to the values of this frame, and control is returned to Main.

SUBROUTINE DTUPK (IDREC)

Main calls subroutine DTUPK after calling HKPRNT for every experimental data record read, from the second record on. During program execution they are, stored in core, two major frames of raw data in IBUF and three major frames of housekeeping in IHK. DTUPK uses this information to gather and store 2 major frames of bit streamed data and its flag fields as well as other information needed to form revolutions. Saved items are described below. For each call to DTUPK saved items are first moved from the (2) to the (1) index, then data and "other information" is unpacked from IBUF (j,1) into item (i,2). In this fashion, housekeeping from IHK (i, 2) applies to the major frame being unpacked. (See "General Program Logic"). Double precision data and MIP-PSI times are pointed to in the IBUF array through an EQUIVALENCE statement. The fact that these times can be missing and/or mixed up leads to complication.

Saved parameters are passed to REV in COMMON/IRBLK/, and are as follows:

IDAT(320,2)- the bit streamed data
from IBUF (33+8N,1), IBUF (34+8N,),
and IBUF (35+8N,16) 16 left bits
only where N=0, 127 (for each minor frame)
(2.5 words from 128 minor frames =320 words)

IFLG(128,2)- error bits in a minor frame
from IBUF (38+8N,1) 7 right most
bits only. Where N=0, 127 for each minor frame.

TIM(4,2)- times of MIP or PSI pulses
if IREF = missing, no TIM's saved
if IREF = 0 MIP's saved
TIM(1,2) from IBUF(9,i)
TIM(2,2) from IBUF(10,i)
TIM(3,2) from IBUF(11,i)
if IREF = PSI's saved

TIM(i,2) from IBUF(12,i)

TIM(2,2) from IBUF(12,i)

TIM(3,2) from IBUF(14,i)

NOTE: TIM(4,2) is inserted in SUBROUTINE REV

- a check is made for the second MIP or PSI pulse being in the first slot. SPIN is computed as wheel SPIN RATE from IBUF(1057,i) and IBUF(1058,i) (a double precision variable). Then SPIN = (2Π/wheel spin rate) + .001. Now if TIM(i,2) is non-missing and is greater than or equal to SPIN, TIM(3,2) = TIM(2,2) and TIM(2,2) = TIM (1,2) and TIM (1,2) is set to missing.

ISTAT (2) - status from IHK(10,2)

IREF (2) - reference from IHK(15,2)

IBA (2) - Bragg angle from IHK(13,2)

ISAG (2) - sungate angle from IHK(12,2)

The above four items are from IHK(i,2) unless it is missing. If it is missing and IHK(i,1) = IHK(i,3) then the item is set equal to IHK(i,3)

DPDAT(15,2) - double precision data where

(1,2) is day of year of regular field from IBUF(2,i)

(2,2) is seconds of year of regular field from IBUF(3,i) $*10^{-3}$

(3,2) right ascension of spin axis (radians) from IBUF (1065,i), (1066,i)

(4,2) declination of spin axis (radians) from IBUF(1067,i) (1068,i)

(5,2) right ascension of roll axis (radians) from IBUF(1069,i)

(6,2) declination of roll axis (radians) from IBUF(1071,i), (1072,i)

(7,2) right ascension of aspect reference axis (radians) from IBUF(1073,1), (1074,1)

(8,2) declination of aspect reference axis (radians) from IBUF(1075,1) (1076,1)

(9,2) probable error of attitude solution (arc-min) from IBUF(1077,i), (1078,1)

(10,2) attitude flag field (see table 10) from IBUF (179,1), (1080,i)

(11,2) wheel spin rate (radians/sec) from IBUF(1057,1), IBUF(1058,i)

(12,2) through (15,2) are spares

SUBROUTINE REV(NREC)

Subroutine REV is the heart of CALO. Here, data that have been gathered, unpacked, interpreted and stored by HKUPK and DTUPK are finally combined to form revolution records. Subroutine REV is called by MAIN for every record experimental data read in a file from the third record to end. NREC, the passed parameter is simply the experimental data record counter, and is used by REV to initalize certain parameters at the start of each new file being processed.

Subroutine REV considers one major frame's worth of data each time it is called, although certain information from the succeeding major frame is needed and used in the determination of revolutions. Thus, generally REV works with data passed by DTUPK in COMMØN/HKBLK/ in the item (i,1) arrays, and housekeeping passed by HKUPK in COMMON/HKBLK/ in IHK(i,1).

First REV determines if there are any revolutions to process in this frame. If status, or reference as determined in DTUPK is missing or if status =2 and Sun Gate angle are missing a counter is incremented* and control returns to MAIN. If the first MIP-PSI, TIM(1,1), is non-missing, and we have previously saved a spin rate (SPINL is non-missing) then we proceed with processing; otherwise if TIM(1,1) or TIM(1,2) is missing a counter is incremented* and control returns to MAIN. However, if both are non-missing, SPINL is computed as TIM(2,1)-TIM(1,1) and processing continues.

Next REV determines how many revolutions there are to process. As TIM(1,1) and SPINL now must both be non-missing, if TIM(2,1) and/or TIM(3,1) are missing, Times are inserted as TIM(missing,1) =TIM(missing -1,1) + SPINL. Now the number of revolutions to process "NTIM" is determined; there are 2 revolutions to process unless: 1) if TIM(3,1) is less than TCØN (128./800.) there are 3 revolutions to process; or 2) if TIM(2,1) is greater than TCØN there is only one revolution to process. Next, the time of the end of the last revolution,

*See Table 4

called TIM(NTIM + 1,1) is set as the time of the first MIP-PSI of the next frame plus TCON.

Status and reference are now checked. If they are not the same in this frame and the next, NTIM is decremented by one, and a flag is set indicating that the last revolution will not be processed. Also, the seconds of this frame and the next are checked. If the time difference is within $\pm$ 1 sec of TCON the frames are considered to be consecutive. If the frames are not consecutive, NTIM is decremented by one and a flag is set indicating that the last revolution will not be processed. NOTE: no check is made for a day change, so the last revolution of the frame preceding a change of day will always be thrown out.

Finally, before processing of revolutions begins a check is made on the first time of the next frame to process. If the first time is missing and the second is non-missing, the time computed as TIM(NTIM + 1,1) for this frame is inserted so that the next frame will have a start time.

Next, the bit streamed data from this frame and the next is unpacked into 8 bit "words" into the array IBYT, so that markers can be found. (For status 0, no markers are looked for; for status 1 and 2 a marker is 20 consecutive bits on (1), starting on an 8 bit "word"; for status 3-5 a marker is 8 bits on, i.e. an 8 bit "word" $=255_{10}$).

Processing of revolutions is now begun, in a loop from 1 to NTIM (the number of revolutions in this frame). The IBYT array is searched for a marker (depending on the status) whose "time" lies between the times of the MIP or PSI pulses defining this revolution. (The diagnostic parameters NOMARK and NBMARK described in Table 4 are utilized if no marker can accurately be found in this range). The "time" of the marker is computed to the accuracy of one bit, from its location in the IBYT array. Spin is computed as the difference of the MIP or PSI pulses defining this revolution, and stored in XD(10). Time of the revolution is computed as the time of the start of the frame plus the time to the MIP or PSI pulse defining the start of the revolution.

DAY and SECS, stored in DPDAT(1,1) and DPDAT(2,1) are adjusted if a change of day occurred at this point.

Next the unpacking and storing of data occurs. As this is done depending on status, the logic for each of the three options is described separately below. Table 12 describes arrays, flags and counters used for the unpacking processes.

A. FOR STATUS 3,4,5

512 8 bit bytes of data are collected, one at a time from the IBYT array, starting at the first IBYT element after the marker for this revolution. The minor frame location of each data item collected is computed and the flag field checked. If the flag field of the minor frame is non-zero, the data item is set equal to a missing code (255_{10}) and a counter IFIX is incremented. Data items are packed, 2 per word into the array IRDAT, such that IRDAT(1) = data item (1) *256 + data item (2) . . . IRDAT(256)=date item(511) *256 + data item(512). NEVN, the number of events in a revolution is always set equal to 512.

B. FOR STATUS 1

An event for status 1 and 2 consists of 20 bits of data; therefore, starting with the bit following the marker, 256 data words are unpacked from the array IDAT into the array IRDAT. Next, the 256 data words are examined in turn. If an event is non-zero, and the flag field(s) of the minor frame or frames in which it occurred are zero, a counter NEVN is incremented and the event is stored in IBUF(NEVN). IF the flag field test was not passed, the counter IFIX is incremented and the next event is considered. This process continues up to 256 times, or until an event is examined that is zero. It is then assumed that all the data for the entire revolution have been stored IBUF. Next the "stuck word" is checked for. If NEVN=1 and the first event of this revolution is equal to the first event in the previous revolution, NEVN is set equal to zero.

C. FOR STATUS 2

The collecting of status 2 data is more complicated than the other statuses because data are collected from the sungate to the Bragg angle, rather than from a marker to the next. Therefore, for each "revolution" as defined by REV, some of the data belongs to the previous revolution and some to this revolution. Using Table 12 the logic is as follows:

Having found a marker, if status is not equal to 2, LOUT is set equal to zero. Also, if the revolution is thrown out, LOUT is set equal to zero. If status is equal to 2, LGET is set to zero and starting with the bit following the marker, 256 20 bit data words are unpacked from the array IDAT to the IRDAT array. Looping through the 256 data words, first if an IRDAT element equals zero, the end of data is assumed and the loop is exited. Next, the flag fields are checked as described in status 1, with IFIX being incremented and the next event examined if the flag fields are non-zero. The azimuth is then unpacked, giving the following options:

1). It is $\geq$ sungate *16+8; then, if LOUT=0, go on to the next event (i.e. this is the end of a revolution that we do not have the beginning of).

Otherwise, increment NEVN and store the event in the IBUF array such that IBUF(NEVN)=IRDAT(I).

2). It is < sungate *16+8; if LGET=0 this is the first event of the next revolution so counters are stored and reset as follows:

ISPR(12)= NEVN; ISPR(11) = IFIX; NEVN = 0; IFIX = 0; LGET = 1;

LOUT = LOUT + 1. In either case, next NEVN is incremented and the event is stored in IRDAT such that IRDAT(NEVN)= IRDAT(I).

This process continues until either an IRDAT element is examined that is equal to zero, or all 256 events have been examined. If LGET was never set to 1 in the loop (i.e. the first event of the next revolution was never found)

the counters are stored and reset at this time. Next if LOUT >1 the stored buffers are output. Then the IBUF array is set equal to the missing code, and processing continues as for the other statuses except that the stored buffers are not output at the time they are output for the others. In this fashion, for each status revolution, the first half of the data is collected and housekeeping etc. prepared for output. When the next revolution is being processed the second half of the data is collected, the revolution is output, then housekeeping etc. prepared for output.

D. FOR STATUS 0

Status 0 is assumed to have no data. Revolutions are output as for other statuses with the following exceptions. NEVN is not necessarily zero; nor is the data buffer necessarily set to the missing code. "Rates" are not calculated, and the South Atlantic Anomaly flag is not computed.

Data having been unpacked, revolutions are next prepared for output, as described below, with the exceptions as noted above.

First the five rates, ANTI, BUSY, UCR, TRIM and LLC are approximately assigned to this revolution. If we let frame 'A' be the frame in which this revolution occurs, frame 'B' is the next frame (frame A + 1) and frame 'C' is equal to frame A + 2. Then if the MIP or PSI pulse defining the beginning of this revolution is > 16, rates are always assigned as the rates from frame 'C'. If the MIP or PSI pulse is $\leq$ 16, the rates for this revolution are set equal to zero unless this is the first revolution in this frame, and all rates in the previous revolution are zero. Then rates are assigned to this revolution from frame 'B'.

Next, REV calls GOBIT to interpolate for the orbital elements associated with this revolution. Orbital information and housekeeping is then moved into the output buffers. ASPECT is called to calculate right ascension and declination of the aspect axis. Next the South Atlantic Anomaly flag is calculated.

If status =0 it is set to missing. If status =1, HV7 and HV8 are considered. If status = 2-5, HV1 thru HV5 are considered. Then, if any one non-missing value considered is greater than 292, the flag is set to 1. If all are missing, the flag is set to missing. If all are non-missing and all are equal 292 the flag is set to zero.

Events that were stored in the IRDAT array are next moved to the output buffer IBUF, and (for all except status 2 data) subroutine OUTPUT is called to write the revolution onto tape.

Next, the IBUF array is set to the missing code, and the next revolution is considered.

When all revolutions in a major frame have been considered, control returns to MAIN.

SUBROUTINE GOBIT (DAY, SEC, ICALL)

This subroutine is called by subroutine REV once for each revolution to be output. Its purpose is to interpolate in time to attach orbital information to a revolution. The array DX(9) is computed in GOBIT from the array X(14,NOB) that was stored by subroutine OBIT. (See table 6 for a description of the X array items). The DX(9) array is then passed back to REV through COMMON/IOBBLK/, and set equal to the XD array such that XD(1) = DX(1), XD(2)=DX(2) . . . . XD(9) = DX(9). This procedure aligns the DX elements for output in the COMMON/OUTBLK/, such that of the double precision variables output, DX(1) will be the 16th, DX(2) the 17th . . . DX(9) the 24th.

The logic of GOBIT is as follows:

DAY and SEC are the computed time of the revolution being processed. ICALL is the number of times GOBIT has been called this file (i.e. it is reset to zero for each file). Assuming that the X array is time ordered, it is searched for the first time (using X(1,i) and X(2,i)) that is greater than or equal to the time of this revolution. The (index -1) of this occurrence is saved and called "L". The start location of the search was set to i if ICALL =1; it is now set to L to save searching time for the next revolution.

If no time was found that meets the above conditions or if L=0, the message "CANT FIND ORBIT TIME FOR DAY = . . . SEC= . . . D1, D2, SEC1, SEC2= . . . , . . . , . . . , . . . " is printed where DAY is the passed parameter "DAY" and SEC is the passed parameter "SEC" and D1, D2, SEC1, SEC2 are the first and last day of the saved X array, and the first and last seconds of the X array. Control then returns to REV which will still output this revolution output. NOTE: NO MISSING CODE OR INDICATION OF THIS OCCURRENCE IS INCLUDED IN THE OUTPUT RECORD. Where this information is critical the user

must refer to the CALO printed output to determine which revolutions are affected.

Assuming a time was found in the array, four time differences are computed

DT = SEC - X(2,L)

T1 = X(2,L) - X(2,L-1)

T2 = X(2,L + 1) - X(2,L-1)

T3 = X92,L + 1) - X(2,L)

NOTE: Although a check and fix is made on DT being affected by crossing over a day, NO CHECK IS MADE ON T1, T2, or T3.

Next, code is looped through for each item to be computed. The loop index "I" goes from 6, 14 referring to items of the X array. For I = 11 and I = 13 special code is executed to assure that the resulting DX computed items are in the proper range. (This "special code is best described by reading the code itself). Generally, for each of the 9 items to be computed X(I,L), X(I,L-1) and X(I,L + 1) are saved as XI, XMI and XPI respectively. With proper constraints on the possibility of multiplying by zero the following equation is computed.

A=(XI-XM1)/T1 + (T1/T2)* [((XP1 - XI)/T3) - ((XI -XM1)/T1)]

Given the above A the resulting DX array items are computed as shown in Table 11.

Control is then returned to REV.

SUBROUTINE ASPECT (DTHETA)

This subroutine is called by REV immediately before each revolution is output. It calculates the right ascension and declination of the spacecraft, and returns the values in the D array (see table 13). The subroutine argument DTHETA is the time of the MIP or PSI of this revolution, divided by the SPIN (as calculated in REV) all times 2Π.

[DTHETA= (TIM(K,1)/XE(10)) *6.2832.] D(3), D(4), D(7) and D(8) as described in table 13 are inputs to the routine, with D(7) and D(8) being recalculated by the routine and D(12) and D(13) being calculated. A listing of the code of ASPECT best indicates the equations used in the calculations.

SUBROUTINE OUTPUT

This subroutine is called by REV for each revolution to be written to tape. The appropriate tape number and file number were read by MAIN in the namelist and are passed to OUTPUT through COMMON/TBLK/. The output buffers are formed in subroutine REV and are passed through COMMON/OUTBLK/. A detailed description of the output record is found in table 13. Each revolution record to output is 1432 bytes long, as declared in a data statement. These are blocked 5/block, as defined on the DD statements for the output tape. Thus, the physical record length on the tape is 7160 bytes.

The first time OUTPUT is called, spare output elements are set to missing, and a call is issued to MOUNT, to mount the output tape and position it at the correct file.

Whenever OUTPUT is called by REV, a call is issued to FWRITE to write the revolution onto tape, and control returns to REV.

ADDITIONAL ROUTINES

POSN(1,NTAP,IFILE). This FORTRAN callable routine positions a tape mounted on unit =NTAP to file IFILE. The first argument indicates that the next operation on the tape will be a forward read.

MOUNT(1,NTAP,IDTI,NFIL). This routine mounts the tape named "IDTI" on unit NTAP at file NFIL. The first argument is as above.

FREAD(IBUF,NTAP,NBYTES,&850,&800). Reads a record of length NBYTES from unit NTAP into contiguous core locations starting at IBUF. Transfer is to statement 850 on EØF and statement 800 on an I/O error.

FWRITE(D,JTAP,LENG). Writes a record of length LENG onto unit JTAP from contiguous core locations starting at D.

SHIFTL(IY,N). In line function provided by PARAM=XL Fortran compiler extension to perform a left shift of N bits on word IY.

LØR(IX,IY). In line function provided by PARAM=XL Fortran extension to logically OR, IX and IY.

ADDITIONAL ROUTINES (CONTD.)

GBYTE (PCKD,UNPK,INOFST,NBIT)

GBYTES (PCKD,UNPK,INOFST,NBIT,NSKIP,ITER)

PCKD: The fullword in memory from which unpacking is to begin: successive fullwords will be fetched as required.

UNPK: The fullword in memory into which the initial BYTE of unpacked data is to be stored; subsequent BYTES will be stored into successive fullwords as required.

INOFST: A fullword integer specifying the initial offset in bits of the first BYTE, counted from the leftmost bit in PCKD.

NBITS: A fullword integer specifying the number of bits in each BYTE to be unpacked. Legal BYTE widths are in the range 1 - 32: BYTES of width .LT. 32 will be right justified in the low-order positions of the UNPK fullwords, with high-order zero fill.

NSKIP: A fullword integer specifying the number of bits to skip between successive BYTES. All non-negative skip counts are legal.

ITER: A fullword integer specifying the total number of BYTES to be unpacked, as controlled by INOFST, NBIT and NSKIP above. All non-negative iteration counts are legal.

NOTES: 1). A multiple -BYTE access (GBYTES) with iter=0 (but not 1) is exactly equivalent to a single-BYTE access (GBYTE).

2). An error detected in the calling sequence of either GBYTE or GBYTES suppresses BYTE access, and sets the first element of UNPK = X'FFFFFFFF'.

TABLE 2

NAMELIST/IPTRIG/

1.	NITR	The number of items that will cause a print trigger currently set=29. It is passed in COMMON/TRIGBL/.
2.	ITR	The indices of the items that will cause a print trigger. Dimensioned ITR(40), it is passed in COMMON/TRIGBL/. It is currently set =1, 9, 10, 11, 12, 13, 14, 15, 35, 36, 37, 38, 39, 40, 2, 3, 4, 5, 6, 7, 8, 27, 28, 29, 30, 31, 32, 33, 34. NOTE: The indices are the same as the "ITEM NUMBER" of the integer outputs.
3.	LIM	The limits for each "ITR" which if strictly exceeded (+ or -) will cause a print trigger. Dimensioned LIM(40), it is passed in CØMMON/TRIGBL/. It is currently set LIM= 0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,4,4,4, 4,4,4,4,1,18,1,30,1,1.
4.	IPALL	A flag, passed in CØMMON/TRIGBL/ which if non-zero will cause every major frame's housekeeping to be printed. Currently set =0.
5.	IP2	A flag, passed in CØMMON/TRIGBL/ which if non-zero will cause right ascension and declination to also be checked for a print trigger. It is currently set =1.
6.	IPNUM1	The number of items to be printed on line 1. Passed in CØMMON/TRIGBL/, it is currently set =20.
7.	IPNUM2	The number of items to be printed on line 2. Passed in CØMMON/TRIGBL/ it is currently set =21.

TABLE 2 (CONTD.)

8.	IMC	The missing code inserted for unavailable housekeeping items. It is passed in CØMMON/HKBLK/ and is set =1.
9.	NPAR	The number of parameters examined to collect a frame of housekeeping. It is passed in COMMON/HKBLK/ and NPAR=38.
10.	JPAR	The number of housekeeping items collected in a major frame. It is passed in CØMMON/HKBLK/ and currently =50.
11.	JTAP	The tape unit number for the output tape, passed in CØMMON/TBLK/ and set =11.
12.	JFIL	The file number to write to on unit JTAP. It is passed in CØMMON/TBLK/ and normally =1.
13.	NTAP	The tape unit number for the input tape. It is passed in CØMMON/TBLK/ and NTAP=10.
14.	NFIL	The first file to read from on the input tape. It is passed in CØMMON/TBLK/ and normally =1.
15.	IDT1	Dimensioned (2), it is the input tape number. It is passed in CØMMON/TBLK/ and normally changes with each program execution. It is entered in the form IDT1='CUxxxx'.
16.	IDT2	Dimensioned (2), it is the output tape number. It is passed in CØMMON/TBLK/ and normally changes with each program execution.

TABLE 3

MAIN PROGRAM COUNTERS

IDREC -	Counter of the number of experimental data records in each input tape file.
IERR -	No. of bad reads on input tape. If IERR exceeds 10, all processing stops.
IFILE -	Input tape file counter.
IOREC -	Counter of number of orbital records in each input file.
ISUM(6)-	Counters of the number of revolutions for each status (0-5) processed. They are printed at the end of a successful run. They are passed thru COMMON /SUMBLK/ and are incremented in subroutine REV.
JERR -	No. of bad record types on the input tape. If JERR exceeds 10, all processing stops.
KSUM(6)-	Counters of the number of revolutions of each file. They are printed as processing of each file is completed.
LREC -	The record number of the last EOF encountered.
NBMF -	No. of minor frames examined that were out of order. This number is printed at the end of each successful run.
NFILL -	No. of minor frames thrown out due to bad flag fields. This number is printed at the end of a successful run.

TABLE 4

The four diagnostic parameters at end of each file printout from CALOO are the following:

1). NOREF - The counter is incremented if reference or status is missing or if status = 2 and sungate are missing. The counter refers to the number of major frames in which no revolutions were processed for the above reasons.

2). NLØUT - If a status change occurs the last revolution of the old status is not processed and this counter is incremented.

3). NBMARK - A marker has been found but the flag field indicates error bits. The marker is therefore thrown out and the next marker is considered. A counter is incremented. NOTE: this could also cause NOMARK to be incremented.

4). NOMARK - No marker is found between the MIP's defining a revolution. NOTE: If BAD FLAG caused a marker to be thrown out and it was real then both counters would be incremented.

NOTES: These parameters are calculated in subroutine REV passed in CØMMON/SUMBLK/, and printed in MAIN.

HV5 IHK(6,3)	> 291 < 293	> 291 < 345	> 393 < 1124	> 393 < 1124	> 356 < 394	> 393 < 1124
HV6 IHK(7,3)	> 291 < 293	> 393 < 1124	> 291 < 345	> 291 < 345	> 291 < 345	> 291 < 345
HV7 IHK(8,3)	> 291 < 293	> 393 < 1124	> 291 < 345	> 291 < 345	> 291 < 345	> 291 < 345

When the value of an item listed meets any of the six inequalities for that item, a counter is incremented for that status. The status with conditions most often met is the status assigned to this major frame. However, if more than one status meets the maximum number of conditions, the assigned status is declared as missing.

TABLE 9

REFERENCE AND RATES

A. REFERENCE - inserted in IHK (15,3)

Day for reference - IHK(48,3)

= get D(6330) bit 6 if =0 get D(62,30)

bit 7

if =1 get D(63,30)

bit 5

B string - IHK(49,3)

= get D(96,72) bits 1-8 if $\leq$ 64 IHK(49,3)=0

if $\leq$ 64 IHK(49,3)=1

A string - IHK(50,3)

= get D(96,95) bits 1-8 if $\leq$ 64 IHK(50,3)=0

if > 64 IHK(50,3)=1

If IHK(48,3), IHK(49,3) or IHK(50,3) are missing then IHK(15,3) is left set to the missing code.

Otherwise IHK(48,3)=1, unless IHK(49,3)=0 and IHK(50,3)=1 then IHK(15,3)=1

B. RATES: inserted as follows:

IHK(17,3)=UPPER CUT REJECTS

IHK(18,3)= RISETIME (missing for status 3,4,5)

IHK(19,3)= LOWER LEVEL CROSSINGS

IHK(20,3) = BUSY

From Table 7 we see 7 bytes were saved for the rates in IHK(41,3) thru IHK(47,3). These were saved from D(98,NMF) all 8 bits.

TABLE 9 (CONTD.)

To decode rates, if any one of the seven saved bytes are missing, all rates are left set to the missing code. Otherwise

1). Status = 3,4,5

ANTI = IHK(16,3) = IHK(41,3) (bits 1-8) *128 + IHK(42,3) (bits 1-6*) *2

BUSY = IHK(20,3), = IHK(42,3) (bits 7-8) *8192 + IHK (43,3) (bits 1-8) *32
+ IHK (44,3) (bits 1-4) *2

UCR = IHK(17,3) = IHK(44,3) (bits 5-8) *512 + IHK (45,3) (bits 1-8) *2

LLC = IHK(19,3) = IHK(46,3) (bits 1-8) *512 + IHK (47,3) (bits 1-8) *2

2). Status 0, 1, 2

BUSY = IHK(20,3) = IHK(41,3) (bits 1-8) *16 + IHK (42,3) (bits 1-3) *2

ANTI = IHK(16,3) = IHK(42,3) (bits 4-8) *32 + IHK (43,3) (bits 1-4) *2

RTIM = IHK(18,3) = IHK(43,3) (bits 5-8) *512 + IHK (44,3) (bits 1-8) *2

UCR = IHK(17,3) = IHK(45,3) (bits 1-8) *8 + IHK (46,3) (bits 1-2) *2

LLC = IHK(19,3) = IHK(46,3) (bits 3-8) *512 + IHK (47,3) (bits 1-8) *2

*bit 1 = MSB

TABLE 10

The attitude flag field contains 20 bits of information. The flag field is in IBM double precision floating point format. When the double precision floating point word is set equal to an integer, then the least significant 20 bits of the 32 bit integer contain the following information. Bit 1 is the least significant bit and when the respective bit is set to one, the condition is present.

Bit	Significance
1	A gas firing has occurred
2	Roll angle ϕ was extrapolated
3	Pitch angle η was extrapolated
4	Aspect angle B_s was extrapolated
5	Spin rate ω was extrapolated
6	Roll angle ϕ was interpolated
7	Pitch angle η was interpolated
8	Aspect angle B_s was interpolated
9	Spin rate ω was interpolated
10	Roll angle ϕ was calculated from a star solution
11	Pitch angle η was calculated (in day time from sun sensor, at night from a star solution)
12	Aspect angle B_s was calculated
13	Spin rate ω was calculated
14	Roll angle ϕ)
15	Pitch angle η) Raw data values

TABLE 10 (CONTD.)

Bit	Significance
16	Aspect angle B_s) were present
17	Spin rate ω)
18	Aspect angle B_s was present from MIP
19	Spin rate ω was present from MIP
20	1 = night at the beginning of major frame
	0 - day at the beginning of major frame

The general guidelines in interpreting the bit settings are as follows: When the lower 9 bits are not set except for bit 6 in the day time, there were good solutions for the attitude state vector. The interpolation of missing values yields, generally, good results. Extrapolation over long periods of time, generally, yields less confident results and should be carefully interpreted by the user. Gas firings should be carefully interpreted because of larger uncertainty in the state vector, particularly during the gas firings.

TABLE 11 - ORBITAL ELEMENTS

NAME	DX	OUTPUT ITEM	
POSITION X	DX(1)	16	= X(3,L) + X(6,L)*DT + (A*DT*DT)*.5

LONGITUDE	DX(8)	23	= X(13,L) + DT*A
LATITUDE	DX(9)	24	= X(14,L) + DT*A

TABLE 12

ARRAYS, FLAGS AND COUNTERS USED

BY REV FOR UNPACKING EVENTS

IBUF(256) - Output buffer for events, passed to OUTPUT in COMMON/OUTBLK/

IDAT(320,2) - The bit streamed data (for 2 frames), collected in DTUPK and passed to REV in COMMON/IRBLK/

IFIX - Counter of the number of events in a revolution that were thrown out due to bad minor frame flag fields.

IRDAT(256) - Temporary storage buffer used in unpacking and storing the bit streamed data.

ISPR(12) - Number of events that are output (i.e. the final NEVN)

ISPR(11) - Number of events thrown out. The final IFIX.

JHK(40) - The output buffer for housekeeping

LGET - Flag used for status 2 data to say we have found the start of the second revolution's data. (i.e. we found the first azimuth less than the sungate *2 + 8)

LOUT - Counter that if non-zero indicates that the last revolution processed was status 2

NEVN - Counter of the number of events in a revolution
