1. INTRODUCTION:

The documentation for this data set was originally on paper, kept in NSSDC's Data Set Catalogs (DSCs). The paper documentation in the Data Set Catalogs have been made into digital images, and then collected into a single PDF file for each Data Set Catalog. The inventory information in these DSCs is current as of July 1, 2004. This inventory information is now no longer maintained in the DSCs, but is now managed in the inventory part of the NSSDC information system. The information existing in the DSCs is now not needed for locating the data files, but we did not remove that inventory information.

The offline tape datasets have now been migrated from the original magnetic tape to Archival Information Packages (AIP's).

A prior restoration may have been done on data sets, if a requestor of this data set has questions; they should send an inquiry to the request office to see if additional information exists.

2. ERRATA/CHANGE LOG:

NOTE: Changes are made in a text box, and will show up that way when displayed on screen with a PDF reader.

When printing, special settings may be required to make the text box appear on the printed output.

MAGNETOMETER JUPITER SUMMARY TAPES (HG COORDINATES)

JUPITER PLASMA SUMMARY TAPES (HG COORDINATES)

77-076A-05A,06A PSFP-00092

This data set has been restored. There were originally 15 9-track, 6250 BPI tapes written in Binary. There are five restored tapes. The DR tapes are 3480 cartridges and the DS tapes are 9-track, 6250 BPI. The original tapes were created on an IBM 360 computer. The DR and DS numbers along with the corresponding D numbers and the time spans are as follows:

DR#	DS#	DD#	FILES	TIME SPAN
DR03788	DS03788	D41959	1	06/19/79 - 06/24/79 *
		D41960	2	06/24/79 - 06/29/79 *
		D41961	3	06/29/79 - 07/04/79 *
DR03789	DS03789	D41962	1	07/04/79 - 07/08/79 *

Proposed Plan for

Submission of Data from the Voyager Plasma Science Experiment to the NSSDC

A. INTRODUCTION

Data from the Voyager Plasma Experiment consists of two basic types:

a. Data on the solar wind obtained during the cruise phase of the mission

b. Data obtained in the magnetosheath and magnetosphere of Jupiter during the encounter phase of the mission.

Both of these sets of data have been subject to an extensive but basically a preliminary analysis and a final more sophisticated analysis remains to be done on both sets. In the following sections we discuss the status of the data analysis for both sets of data and summarize what we expect to deposit in the NSSDC by October 1, 1980.

B. CRUISE DATA

Data has been obtained from both Voyager 1 and Voyager 2 from launch up until the present time. The coverage is essentially complete (tracking is between 50 and 75% for each spacecraft) and has been analyzed to give hourly averages of plasma velocity, number density, and temperature between 1 and 7 AU. These data refer primarily to protons. The analysis of the helium component is not yet in final form.

Higher time resolution data will, of course, be ultimately available. That availability is contingent on a more sophisticated analysis of the alpha particle component which depends in turn on the availability of final values for the interplanetary magnetic field. Depending upon the effort devoted to this analysis, it will be one or two years before a final high time resolution cruise data set is

available. In the meantime we are willing to entertain proposals which require limited amounts of high time resolution data.

As of October 1980, we intend to deposit an hourly average tape which for Voyager 1 contains data obtained between 1 and 7 AU and for Voyager 2 between 1 and 5 AU. The data on these tapes will include plasma flow velocity (speed and two angles), proton number density and temperature. At this point, it is not practical to include data on the helium component.

C. ENCOUNTER DATA

Current State of the Analysis of PLS Data during Jupiter Encounter

The following brief description should make apparent the limitations of the present analysis and define more clearly the data set which we propose to submit to NSSDC.

Figure 1 shows the Voyager 1 trajectory projected onto the Jovian equatorial plane. Also shown is the projection of the symmetry axis of the main sensor cluster (S), which consists of three modulated-grid Faraday cups (the A, B, and C cups). The projection of the normal of the side-looking sensor, or the D cup, is also indicated (D). The prime field of view of the main cluster is roughly a cone of half-angle 45° about the symmetry axis (Bridge et al., 1977), and the field of view of the side sensor is a cone of half-angle 30° about the cup normal. It is apparent from this figure that plasma corotating with Jupiter will flow into the D sensor over most of the inbound leg of the trajectory. Cold corotating flow moves out of the D sensor and into the field of view of the main cluster near closest approach, and out of the field of view of all sensors on the outbound leg. This behavior is shown quantitatively for Voyager 1 in Figure 2, which gives the response of the A, C, and D sensors to cold, rigidly corotating plasma as a function of time along the spacecraft trajectory.

Up until the present, the bulk of the plasma data has been analyzed using only one sensor at a time, the cup of choice being the one looking most nearly into corotating flow at a given point along the trajectory. No analysis has been carried out for highly oblique flows, i.e., when the flow is more than ~30° from any sensor normal. Thus, we have done very little analysis on the outbound legs of either Voyager 1 or Voyager 2. Examples of our inbound analysis of individual cups is shown in Figures 3 and 4. Figure 3 shows the positive ion charge and mass densities from ~45 R_J to closest approach (CA) on Voyager 1. The analysis up to day 64 0300 is of D sensor data; analysis after that time is either A, B, and C sensor data. Figure 4 shows the component of plasma velocity into the D sensor on the inbound leg, derived from the low resolution (L-mode) positive ion spectra. When we analyze only one sensor at a time, we obtain only the component of plasma flow along that sensor normal (e.g., see Belcher et al., 1980). Also shown is the expected component of flow along the D sensor normal assuming rigid corotation. The fact that the plasma is moving at less than the expected corotation velocity as close as 10 R_J to the planet has been one of the most novel results of the PLS analysis (McNutt, et al., 1979; Hill, 1980). An example of one of the best M-mode spectra from the D sensor is shown in Figure 5; we also show Maxwellian fits to various heavy ion species present in the spectra.

The analysis used to obtain the results discussed above uses one sensor at a time. If the flow is reasonably supersonic (Mach four or greater) and is flowing into the sensor at a small angle to the normal ($\lesssim$20°), one can sensibly take the response function of the detector (see Vasyliunas, 1971; Belcher et al., 1980) to be constant. With this assumption, our present analysis provides good estimates of the densities and temperatures of the various ions, as well as their common velocity component along the sensor normal. In some cases, when the flow is close to the symmetry axis of the main cluster, the response function of all

of the sensors in the main cluster can be taken as unity, and the three velocity components from the A, B, and C sensors can be combined to yield a vector velocity. This is, of course, the normal procedure in the analysis of solar wind data. In the Jovian magnetosphere, we can use this procedure only for a limited time around closest approach (cf. Figure 2) and during one spacecraft maneuver near 35 R_J on Voyager 1 inbound. Most of the time the flow is oblique to two or more sensor normals, the response function is very different from unity, and we cannot combine the simple solar wind analysis from two or more cups to obtain vector velocities. However, we still have significant signals in the cups which are oblique to the flow, and there is a large amount of information to be gained from the analysis of that data if we properly account for the effects of the finite response of the sensors. This type of analysis will be done in the future.

Encounter Data to be Submitted to NSSDC

For the Jupiter encounter we plan to submit two sets of data. The first will contain results of the analysis of encounter data performed to date which are discussed above; that is, they will be the data sets which form the basis for the plots of charge density and mass density shown in Figure 3 and for the analysis of plasma velocity shown in Figure 4. It should be possible for outside users to utilize these data with little additional effort.

We also intend to deposit in NSSDC a more basic data set which includes all of the encounter results but which will require a good deal more experience and investment of time on the part of potential users. The basic encounter data set exists in a form which the PLS and MAG experimenters have called "summary tapes." Basically, this data set is only one step removed from the Experiment Data Records (EDR) furnished by JPL. They have been processed to remove bad data, to arrange the data sequentially, etc. In addition they contain the results

of a crude moment analysis to derive plasma parameters. This analysis is usually not valid in the Jovian magnetosphere but it furnishes a useful basis for a qualitative evaluation of the data. We normally use this tape in conjunction with an SEDR (Supplemental Experiment Data Record) tape as a basis for analysis of the encounter data; i.e., the summary tapes, the SEDR, and an appropriate software package form the basis for most analyses which are currently being carried out at MIT.

We feel that it is important that these summary tapes together with adequate documentation be available as a primary data base especially for work which may take place sometime in the future. For example, it may be especially important to have the primary data available for future comparisons with results from Galileo or ISPM.

D. DOCUMENTATION

Adequate documentation exists for most of the material described above. There are significant gaps which we intend to fill by October and although the task is not negligible, it appears to be feasible to submit the data described above and the appropriate documentation by about October 1, 1980.

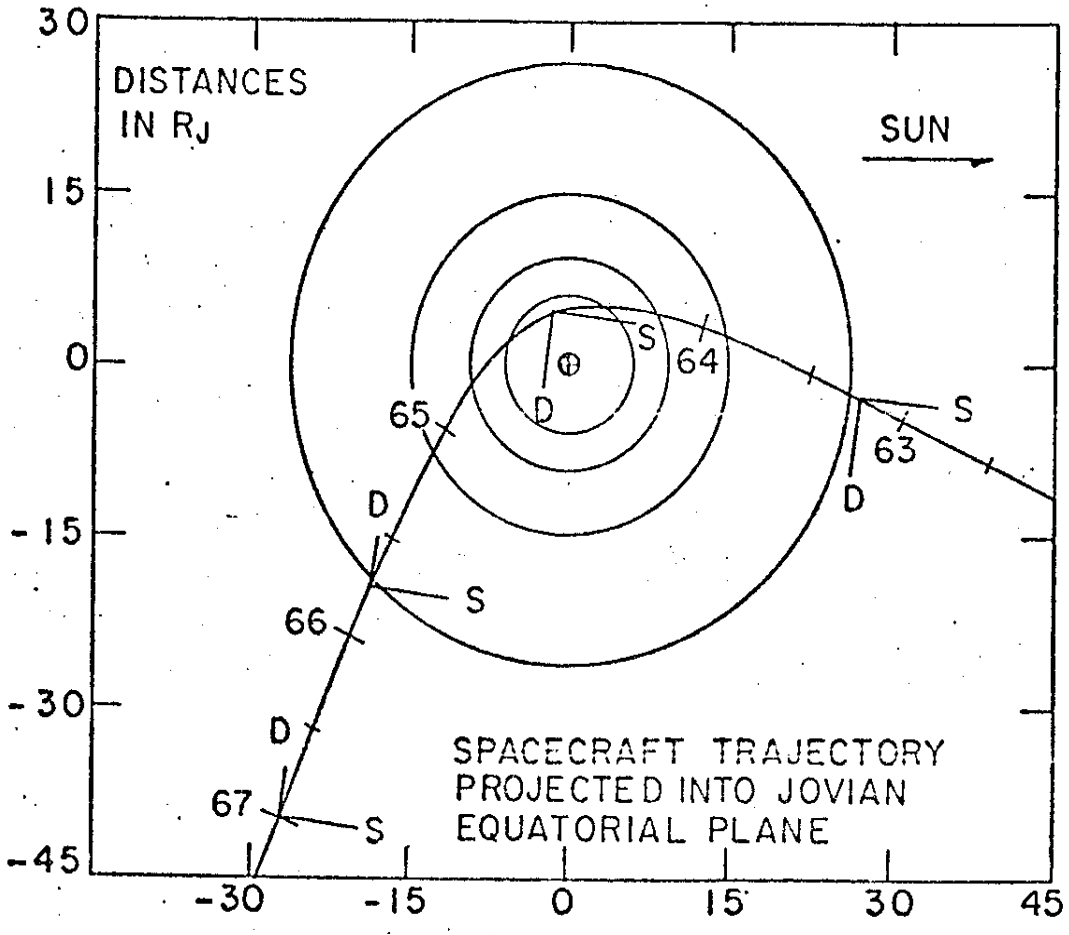

Figure 1: The Voyager 1 trajectory projected onto the Jovian equatorial plane. The line labeled S is the projection of the symmetry axis of the main cluster of Faraday cups, and the line labeled D is the projection of the D cup normal.

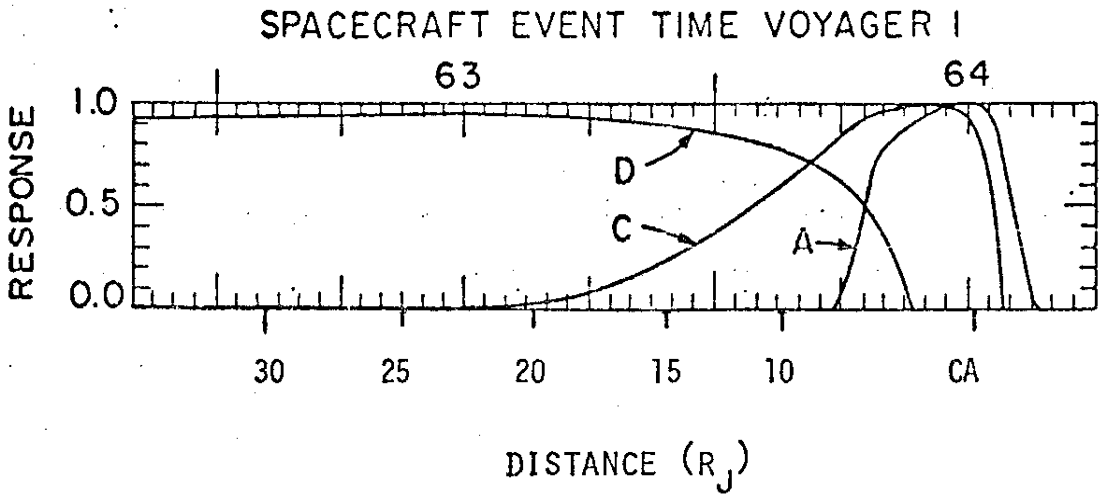

Figure 2: The response of the A, C, and D cups to a cold, corotating beam as a function of time along the Voyager 1 trajectory. The response of the B cup is almost identical to that of the C cup. The response is that fraction of the flux of an incident beam which is measured at the collector plate of the instrument.

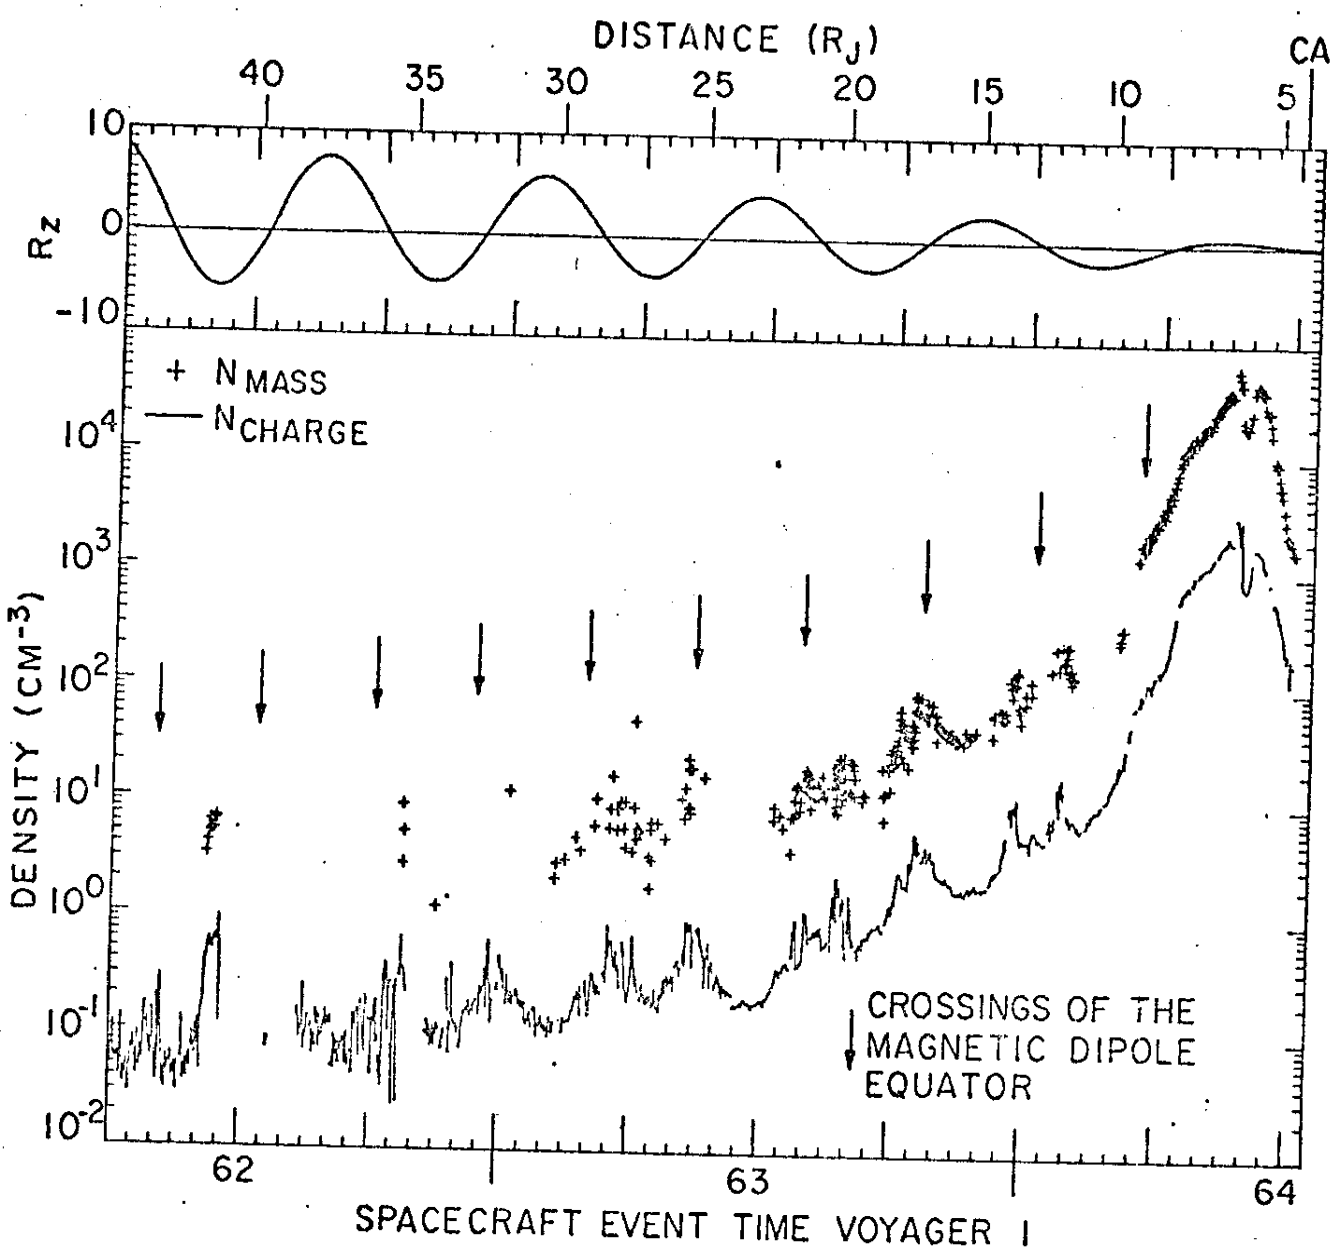

Figure 3: Mass and positive charge density as determined by PLS on the Voyager 1 inbound pass. The crosses represent amu/cc and the solid line total positive ion charge/cc, i.e., $\sum_i n_i Z^*_i$.

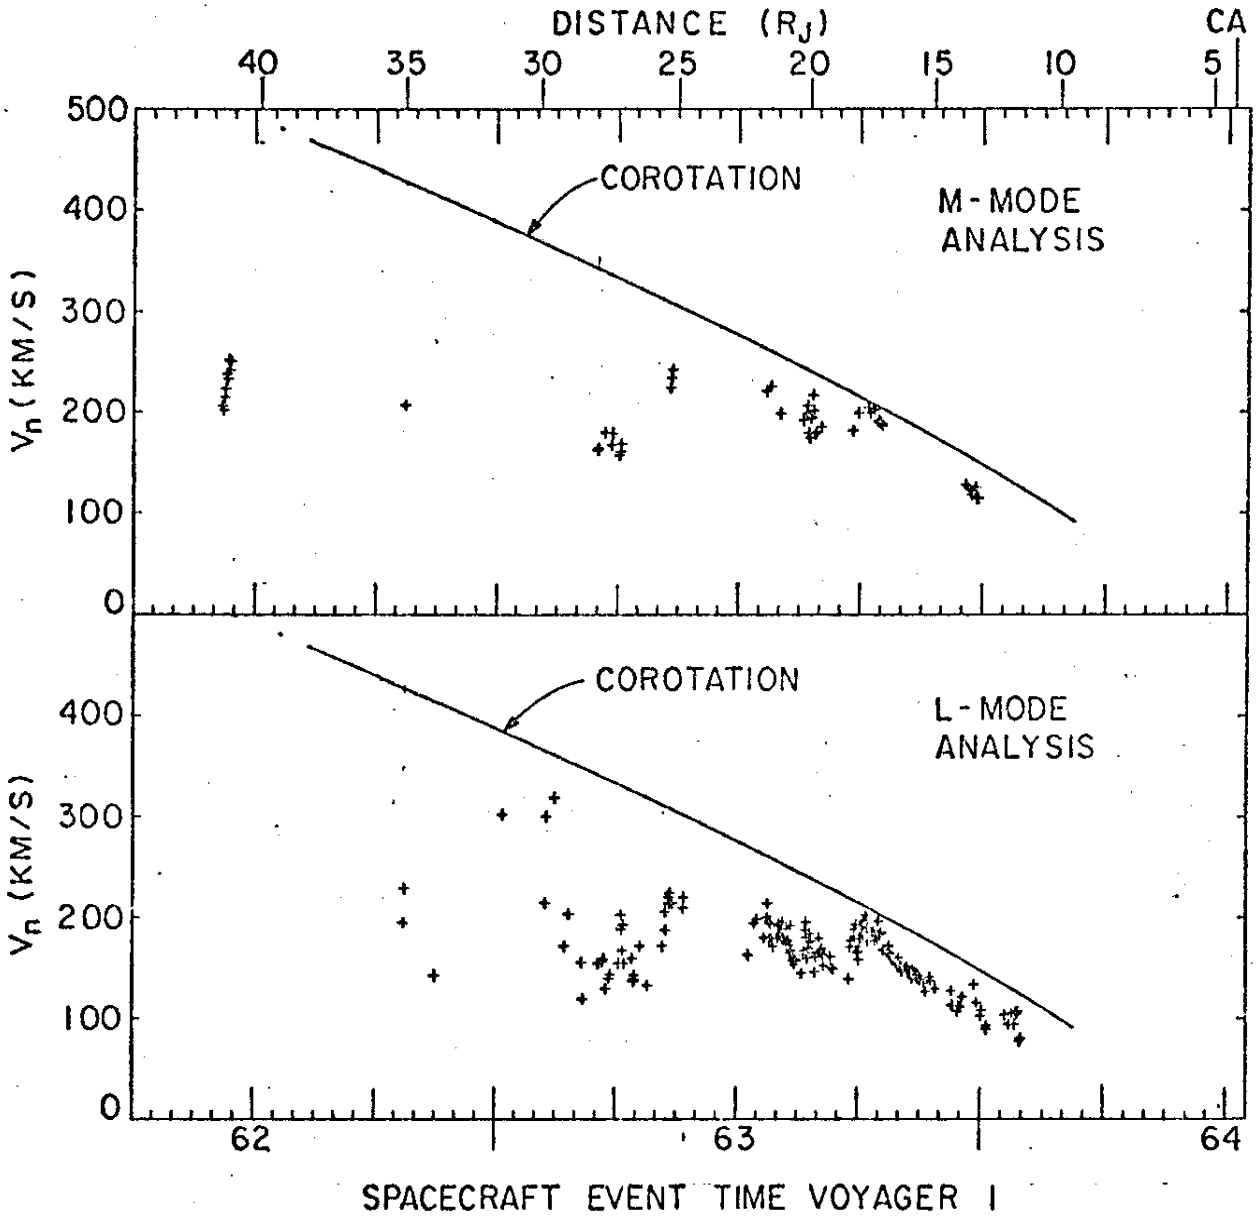

Figure 4: The component of plasma bulk velocity into the D sensor on the Voyager 1 inbound trajectory. The solid line is the expected component of flow assuming rigid corotation.

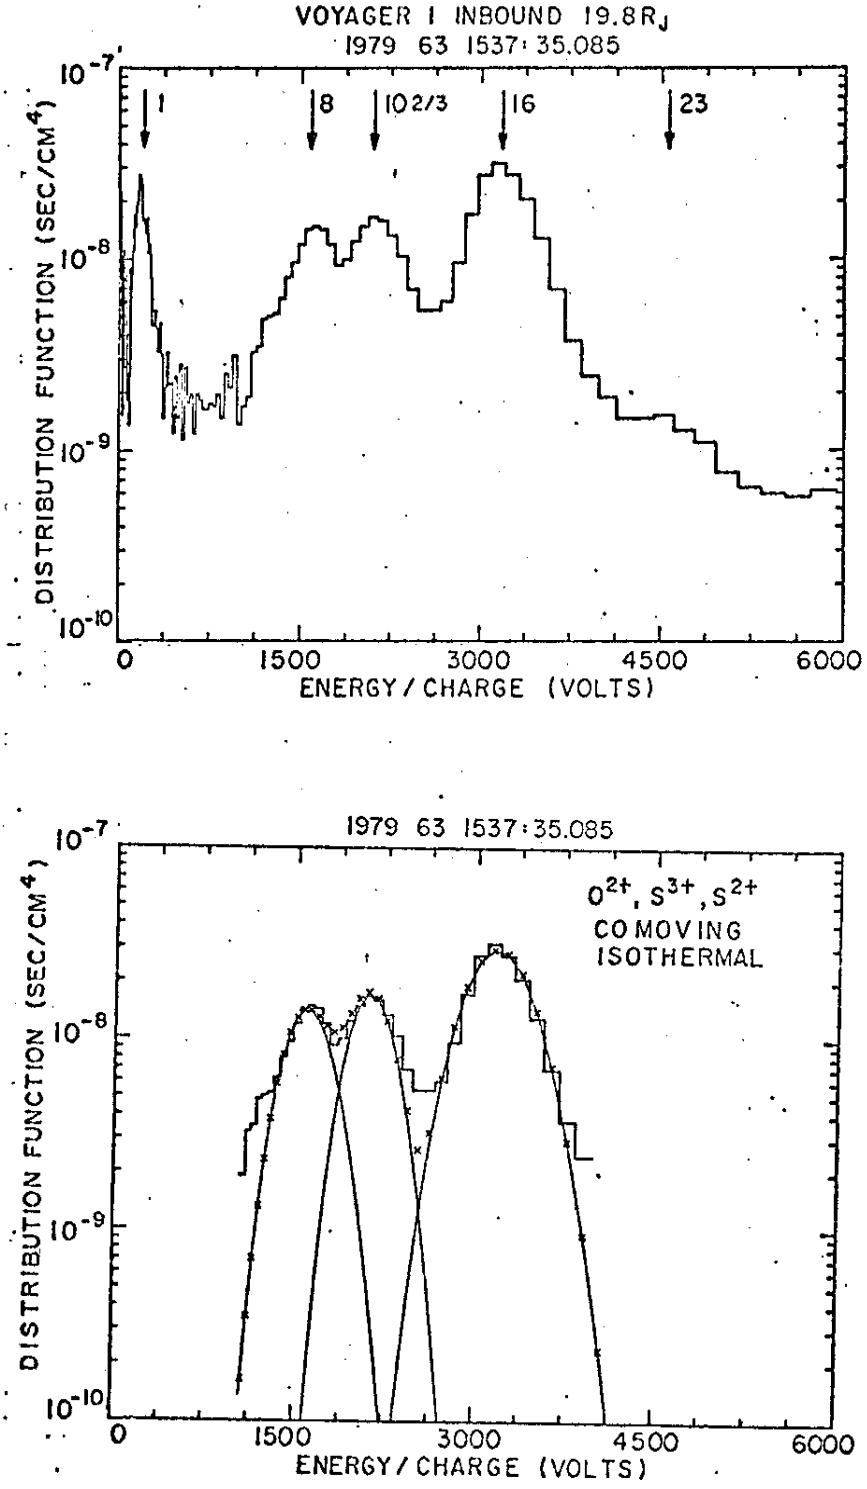

Figure 5: An M-mode spectrum from the D sensor at 19.8 R_J on Voyager 1 inbound. The peaks in energy per charge labeled 1, 8, 10-2/3, 16, and 23 are due to H^+, O^{++}, S^{+++}, O^+ or S^{++}, and Na^+. We also show Maxwellian fits to O^{++}, S^{+++}, and S^{++}.

Voyager Conjoint Data Tape Format For Combined MAG And PLS Analysis

Tapes are IBM standard label, 9 track and contain IBM variable blocked (VB) records. Master tapes are 6250 BPI, distribution copies may be 1600/800 BPI.

There are four distinct types of records: header; magnetometer science; plasma science; and engineering. All Master Library tapes will contain all data record types. Prior to filing of these tapes in the NSSDC at GSFC, any tapes distributed outside the principal sphere of interest (MIT and GSFC), will contain only one type of data (MAG or PLS) plus engineering, unless there is mutual PI agreement to do otherwise.

Engineering records always precede science records. Science records are time ordered by the end time of the PLS data blocks and the begin time of the MAG data blocks. The time tag represents the Begin time of a block.

The first word in each record is an identifier for that type of data. The following table lists the record characteristics and their frequency of occurrence.

Record Type	ID	Rate	Length (Bytes)	Mode
Engineering	ENG	1/12min 1/48min	1092v	GS3,CR1,CR2 CR3,CR4,CR5,CR6,CR7
Low field magnetometer	LFM	1/48sec	2076	All modes
Proton high resolution	M	1/12sec 1/96sec 1/192sec	2540v	CR1 GS3,CR2,CR3,CR4 CR5,CR6
Proton low resolution	I	1/96sec 1/192sec 1/384sec	1056	GS3,CR2,CR3,CR4 CR5,CR6 CR7
Electron	E1/E2	1/12sec 2/96sec 2/192sec 2/384sec	680	CR1 GS3,CR2,CR3,CR4 CR5,CR6 CR7

High field MAG data is not compacted and therefore will not appear on this tape.

The DD card necessary to read this tape is:

```
//ddname DD UNIT=(9TRACK,,DEFER),LABEL=(,SL),DISP=SHR,
//       DCB=(RECFM=VB,LRECL=4224,BLKSIZE=18260,LEN=4),
//       DSN=VOYAGER.CONJOIN1.MAG.PLS,VOL=SER=xxxxxx
```

Each logical record consists of two or more parts. The following diagrams show the different record types and the different segments in each.

ENG - Engineering

Header 32 words	Selected Engineering Data 2 to 240 words

LFM - Magnetometer

Header 32 words	MAG Data 496 words	SEDR 40 words

M - Proton Mode

Header 32 words	Output Data 150 words	SEDR 50 words	Raw Data 256 words	Overlap Variable

L - Proton Mode

Header 32 words	Output Data 150 words	SEDR 50 words	Raw Data 32 words

E1/E2 - Electron Mode

Header 32 words	Output Data 80 words	SEDR 50 words	Raw Data 8 words

Because of the variable length of each record, a word has been added to each record header block to allow the use of FORTRAN in reading this tape. The last halfword of the block contains the count of the number of words remaining in the logical record.

Common Record Header Block

RELATIVE WORD	TYPE*LEN	DESCRIPTION

Note: For Jupiter System III, (B1,B2,B3) are Spherical coordinates while the angles DELTA and LAMBDA are derived from Cartesian coordinates.

Engineering Data Area

RELATIVE WORD	TYPE*LEN	DESCRIPTION
1	I*2	Deck (Eng code 620-672)
	I*2	Value of ENG
2	R*4	"read-out" time of data in seconds past time on record header block
3-240		repeat words 1 and 2 for each new set

Since only engineering parameters which change are entered into the record, the record is of variable length.

SEDR Data Block

RELATIVE WORD	TYPE*LEN	DESCRIPTION
1-2	R*8	TN: epicday of navigation blcck "closest" to data
3-4	R*8	TP: epicday of pointing vector block "closest" to data
5-10	R*4	Spacecraft relative positicn vector and velocity vector in EG: Inertial Sun Equator System (AU,km/sec). Time tag is TN. S3: Jupiter System III Cartesian (Jupiter radii,km/sec) Time tag is TN.
11	R*4	Spacecraft distance from HG: Sun in AU. Time tag is TN. S3: Jupiter in Jupiter radii. Time tag is TN.
12-13	R*4	Spacecraft relative longitude & latitude in radians in EG: Inertial Sun Equator System. Time tag is TN. S3: Jupiter latitude,Jupiter System III longitude. Time tag is TN. Note 0<=longitude<2*pi and -pi/2<latitude<=+pi/2
14-22	R*4	HG: Matrix to rotate data from Inertial Sun Equator System to Inertial Heliographic System. Time tag is TN. S3: Matrix to rotate data from Jupiter System III Cartesian to Jupiter System III Spherical. Time tag is DT.
23-31	R*4	HG: Matrix to rotate data from Inertial Heliographic System to Earth-Orbit-True System. Time tag is TN. S3: Matrix to rotate data from payload to Jupiter System III Cartesian. Time tag is DT.
32-40	R*4	HG: Matrix to rotate data from payload to Inertial Heliographic System. Time tag is DT. S3: Matrix to rotate data from payload to Jupiter System III Spherical. Time tag is DT.
41-50		SPARE

Matrices are left multiplying with elements in the order:

$$\begin{vmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{vmatrix}$$

Time tag TN is relative words 1-2 above. Time tag DT is record header time plus 1/2 the length of the data record.

When MAG(28) switch is on and the record is LFM, the time tag for relative words 32-40 above is record header time plus 47.04 seconds.

SUBJECT: Voyager MAG Summary Tapes: Formats and Coordinates

The Voyager MAG/PLS Summary tapes for Saturn are essentially identical in format to the Jupiter Voyager tapes, only a few names have changed consistent with the particular encounter. For example, where we used System III for the Jupiter encounter (i.e., the "rotating system") we now use for Saturn the L1 coordinate system. L1 is identical to the Desch and Kaiser SLS system, as far as Saturn's rotation period and phase are concerned; see Desch, M. D., and M. L. Kaiser, Voyager Measurements of the Rotation Period of Saturn's Magnetic Field, Geophys. Res. Lett., 8, 253, 1981.

The MAG portion of the Summary Tapes are described on pp. 1.15-1 through 1.15-9 of GSFC-X-694-76-242, "Commonly Used Digital Tape, Disk and Card Formats," (Revised Feb. 1981), and I have attached p. 1.15-4, which shows the relevant blocks of MAG-averages. Notice the components B_1, B_2, B_3. These correspond to B_R, B_T, B_N, respectively, in the (spacecraft centered) Heliographic (HG) coordinate system, for which we also have supplied Jupiter and Saturn encounter tapes. But in the L1 ($\equiv$ SLS) system B_1, B_2, B_3 correspond to B_r, B_θ, B_ϕ, respectively, which are in a spacecraft centered system whose basis is the following set of orthogonal unit vectors (see Fig. 1):

$\hat{r}$, along the Saturn-spacecraft line, positive away from Saturn;

77-0844 05E

$\hat{\theta}$, perpendicular to $\hat{r}$ and parallel to a Saturnian meridian plane, positive southward; and

$\hat{\phi}$, equal to $\hat{r} \times \hat{\theta}$, which is parallel to Saturn's equatorial plane and positive eastward, i.e., in the direction of planetary rotation.

Obviously the absolute directions of $\hat{r}$, $\hat{\theta}$, and $\hat{\phi}$ will depend on the spacecraft position at any instant, but they do not depend on the period or phase of Saturn. On the other hand, on the L1 tapes the angular representation of the field's direction, given by DELTA (δ_{L1}) and LAMBDA (λ_{L1}) on p. 1.15-4 in the "Formats" document, does depend on the planet's period and our chosen phase. These angles reflect the Desch-Kaiser SLS chosen period/phase. The attached sketch (Fig. 2) gives the definitions of these angles. Notice that for an inertially fixed S/C and fields represented in the L1 system λ_{L1} will go through 360° every 10 hours, 39.4 min.

Usually for model-fitting of the planetary field it is the components B_r, B_θ, B_ϕ, and knowledge of the S/C position in the same spherical system that are used, not λ_{L1} and δ_{L1}. Since in model field fitting the S/C position must be represented in a planet-fixed system, i.e., rotating, then the spin period and phase chosen to represent the planet's rotation (SLS in our case) become important.

ABSTRACT

We have discovered that an error was made in computing ion temperatures for some of the results derived from the positive ion data from the Plasma Science (PLS) experiment on the Voyager spacecraft. The reported results directly affected by this error are the ion temperatures in the inner magnetosphere of Jupiter given by Bagenal et al. (1980) and Bagenal and Sullivan (1981) plus a single ion temperature calculated from Voyager 1 data obtained in Saturn's magnetosphere and quoted by Bridge et al. (1981). The ion temperatures quoted for the torus region in the original Jupiter *Science* article (Bridge et al., 1979) and all of the ion temperatures in the middle magnetosphere of Jupiter (McNutt et al., 1981) were derived independently and are unaffected by the error.

DISCUSSION OF ION TEMPERATURE MEASUREMENTS

We are currently reanalyzing much of the positive ion data obtained by the Voyager PLS experiment during the Jupiter encounters. In the course of that analysis it became apparent that some ion temperatures obtained in previous work were a factor of two lower than those derived from the current analysis program. This discrepancy was traced to an error which affected some but not all of the earlier results.

The error, which caused the ion temperature to be quoted at half of the correct value, was introduced because the "ion thermal speed" was defined inconsistently in separate parts of the analysis of the torus data. The energy-per-charge spectra obtained by one of the PLS detectors during the inbound traversal of the Io torus are shown in Figure 5 of Bagenal and Sullivan (1981). In the initial analysis of these spectra each ionic species was assumed to have an isotropic reduced distribution function in velocity space which could be described for a specified direction (such as along the detector normal) by a Maxwellian function

$$f(v) = nw^{-1} (2\pi)^{-1/2} \exp\{-(v-V)^2/(2w^2)\} \qquad (1)$$

involving three independent parameters: the bulk speed of the ions in the specified direction V, the total number density n, and the thermal speed w. For the above form of f(v), w is related to the ion temperature by $w = (kT/m)^{1/2}$ where m is the mass of ion. The error occurred when the values of the ion thermal speed derived from the data in this way were later converted to ion temperatures using the more common definition of $(2kT/m)^{1/2}$ for the thermal speed. Thus the ion temperatures that emerged from the analysis were a factor of two lower than they should have been. Although the values derived for local density and bulk speed are obviously not affected by this error, the underestimate of the ion temperatures has two major effects. First, the incorrect ion temperatures were used to calculate scale heights for different ionic species. Since these scale heights form the basis for the two dimensional plots of plasma density in the torus (as a function of cylindrical radial distance and distance from the centrifugal equator, z), the contour plots given by Bagenal et al. (1980) and Bagenal and Sullivan (1981) are

incorrect. In addition, values of the flux tube content per unit L times the L-shell parameter squared (NL^2), derived using these temperatures, are underestimates by about a factor of $(2)^{1/2}$. The following section contains a summary of published results affected by this error in calculating the ion temperatures.

SUMMARY OF THE EFFECTS ON PUBLISHED RESULTS

The ion temperatures derived by Bagenal and Sullivan (1981) and shown in Figure 7 of that paper should be increased by a factor of two, as should the ion temperatures in Figure 1 of Bagenal et al. (1980) (however, see the following section for a discussion of the inherent uncertainties in the ion temperature determination). The temperatures inside of 10 R_J only, shown in Figure 11 of McNutt et al. (1981), should also be increased by a factor of two. With regard to the single incorrect estimate in Saturn's magnetosphere, the thermal speeds quoted in Figure 5 of Bridge et al. (1981) for ions with mass to charge ratios of 1 and 16 should be 38 and 28 km sec^{-1} respectively, where thermal speed is defined as $(2kT/m)^{1/2}$.

The ion temperatures in the inner magnetosphere of Jupiter were used to extrapolate the local measurements of ion density away from the spacecraft location along magnetic field lines; these extrapolated values of ion density describe the spatial distribution of plasma in the Io torus and were given in the form of density contour plots by Bagenal et al. (1980) and by Bagenal and Sullivan (1981).

Correction of the ion temperatures results in a torus which is more extended in latitude than that shown in these papers. If we approximate the density distribution along a field line as a Gaussian function

$$n(z) = n(z=0) \exp \{-(z/H)^2\} \qquad (2)$$

where the scale height $H \propto (T)^{1/2}$, it is evident that the two-fold increase in temperature means that the torus should be ~40% more extended in the z-direc-

tion. The spatial distribution of torus plasma has been re-calculated in the same manner as Bagenal and Sullivan (1981) using temperatures corrected by a factor of 2. The resulting map of positive ion charge density (in elementary charges/cm^3) is shown in Figure 1.

If we take the boundary of the plasma torus to be defined as the 250 cm^{-3} contour of the electron density map, the total volume was estimated to be $7.7 \times 10^{31} cm^3$ (212 R_J^3) before correcting the temperature. Using the corrected contour map in Figure 1, the volume is increased by 30% to $1.0 \times 10^{32} cm^3$ (287 R_J^3) and is equivalent to a uniform torus with major and minor radii of 6.0 and 1.56 R_J respectively. Only 3.0% (27%) of this volume is occupied by charge densities of over 2000 (1000) cm^{-3} while these regions of high density contribute 9% (48%) of the total of 9.1×10^{34} elementary charges. As an aside, we note that the <u>average</u> density is only 875 cm^{-3}; this is considerably less than values generally used in the literature for the Voyager 1 epoch in studies of the torus.

Values of the quantity NL^2 have been derived using the scale height approximation for the density distribution given in equation (2) and integrating over z to obtain

$$NL^2 = \Sigma\, 2\pi^{3/2}\, R_J^2\, L^3\, n_i(z=0)\, H_i \qquad (3)$$

Thus the erroneous ion temperatures caused the value of NL^2 to be underestimated by a factor of $\sim(2)^{1/2}$.

Values of NL^2 derived from the Voyager data have been used by various authors to calculate rates of plasma diffusion in the torus region (Richardson et al., 1980; Richardson and Siscoe, 1981; Siscoe et al., 1981; Richardson and Siscoe, 1983; Cheng et al., 1983). Tokar et al. (1982a) used the plasma distribution derived by Bagenal and Sullivan (1981) to calculate the dispersion that would be expected if the whistlers observed by the Voyager Plasma Wave experiment had traveled from the ionosphere of Jupiter to the spacecraft. The electrons accompanying the torus ions were insufficient to produce the observed dispersion and Tokar et al. (1982b) inferred that light ions, such as protons, had escaped from Jupiter's ionosphere and populated the mid-latitudes

between the torus and the ionosphere, contributing a further 10%-20% to the total electron content of these L-shells. Correcting the ion temperatures by a factor of two in the warm torus would increase the total plasma content by ~40% which may produce far greater frequency dispersion of the whistlers than observed (however, see the discussion concerning temperature below). Without repeating the work of Tokar et al. (1982) it is not possible to accurately determine the constraint placed by the observed whistler dispersions on the total flux tube content.

Finally, another important quantity that was derived from the PLS ion measurements was the Alfven speed in the torus. Since the Alfven speed is inversely proportional to only the square root of the local mass density, the corrected ion temperatures produce little change in the contour map of Alfven speed shown in Figure 15 of Bagenal and Sullivan (1981). The average time taken by an Alfven wave to travel along field lines between Io and the ionosphere of Jupiter (Bagenal, 1983) should be increased by ~20% to 400 seconds due to the extension of the torus. The range in travel times due to the variation in Io's position in the torus becomes about 200 to 800 seconds.

UNCERTAINTIES IN THE MEASUREMENTS OF ION TEMPERATURES

The ion data obtained inside ~5.7 R_J allowed accurate determination of the temperatures of the major ionic species (Bagenal and Sullivan, 1981; Bagenal, 1984). In this cold inner torus then, the factor of two correction to temperatures discussed above reflects the physical conditions in that region. However, outside of ~5.7 R_J, in the warm torus, there are inherent difficulties in the determination of ion temperatures. We currently feel that an increase of a factor of two in published ion temperatures in that region, although mathematically correct, probably is not physically realistic; on physical grounds an increase in published values of a factor around 1.5 is probably more appropriate in the warm torus for the following reasons. Firstly, the broad velocity distributions of the warm plasma produce a very flat energy-per-charge spectrum in which the individual peaks of the ionic species cannot be resolved. Thus the parameters V, n and w for each species are not well-

constrained by the data. Imposing the condition that all the ions should have the same temperature would reduce the number of free parameters and improve the fit.

However for the isothermal approximation to be valid the time scale for thermal equilibrium between the different heavy ion species must be appreciably less than the characteristic time for diffusive loss. For the thermal (~60 eV) multi-species torus plasma ions the time for equilibration via ion-ion Coulomb collisions is about 5 days and the diffusion time scale is 10 to 100 days. Thus the isothermal assumption is probably reasonable for the bulk of the ions. However new ions are continuously created at pickup energies of 300 to 600 eV and these ions maintain a high energy tail in the ion distribution at energies well above the peak of the thermal distribution. This hot component will broaden the energy-per-charge spectra and increase the ion temperatures derived under the assumption of thermal equilibrium. A preliminary inspection of the high energy tail of the spectrum suggests 10%-20% of the ions are hotter than the thermal population. These numbers are consistent with both theoretical studies (Barbosa et al., 1983; Richardson and Siscoe, 1983) and spectral observations of optical emissions from S^+ ions reported by Brown (1982).

A study of the ionic composition of the warm torus using data from both the PLS detector and the Voyager Ultraviolet Spectrometer is in progress and it is hoped that, as a result of reducing the number of free parameters, the ion temperature can be better constrained. Meanwhile, the original analysis of Bagenal and Sullivan (1981) probably over-estimated the width of the velocity distributions because of the presence of non-thermal tails, and hence we believe the temperature of the thermal ion population outside 5.7 R_J to be only a factor ~1.5 greater than their results, and not the full factor of two. We must be cautious in comparing local measurements made by Voyager 1 in 1979 with remote observations made using ground-based telescopes over a period of several years. Nevertheless, we suggest that the ion temperatures reported here are consistent with the temperatures of S^+ and S^{2+} ions obtained from spectral measurements of line emissions by Trauger et al. (1980), Brown (1981, 1982) and Roesler et al. (1982).

ACKNOWLEGDEMENTS

This work was supported by NASA under contract 953733 to MIT from the Jet Propulsion Laboratory.
